Strep sore throat responds readily to

ILOTYCIN

(Erythromycin, Lilly)

Temperature normal, throat culture negative, usually within twenty-four hours. Notably safe and well tolerated.

dosage: 1 to 1.5 Gm. daily in divided doses.

Lilly

532178

191969 JUL 24 1958

new vistas

for the . . . .

Effective control of seizures, social acceptance, and recognition of employment potential are providing new vistas for the majority of epileptic patients. Accurate diagnosis and adequate therapy, as in present-day management, can be expected more confidently than ever before to restore such patients to as full a life as is compatible with their condition.

DILANTIN® SODIUM

(diphenylhydantoin sodium, Parke-Davis)

Alone or in combination, DILANTIN continues as an anticonvulsant of choice for control of grand mal and of psychomotor seizures. In addition to its notable effectiveness, DILANTIN has little or no hypnotic effect.

DILANTIN Sodium is supplied in a variety of forms—including Kapseals® of 0.03 Gm. (½ gr.) and 0.1 Gm. (1½ gr.) in bottles of 100 and 1,000.

GENERAL

Authors

Manuscripts should be addressed to Arthur H. Wells, M.D., Editor, 915 East First Street, Duluth 5, Minnesota. Telephone RA 7-6636 or JA 5-2319. Original papers prepared for publication solely in Minnesota Medicine will be considered by the Board of Editors providing they fulfill the following editorial standards. Manuscripts should be typed double spaced on white paper with at least 1-inch margins. The original (not a carbon copy) is requested. The title on the first page should be under six words if possible or divided into two parts. The author should give his highest degree, his institutional position or his relationship to a hospital or medical organization which he may be addressing. Pages should be numbered consecutively and the author's last name should appear at the top of each page after the first page.

Biographical references should appear on a separate sheet entitled "Bibliography." They should appear and be numbered consecutively in the order in which they first occur in the text (not alphabetically). Citations in the text require reference numbers if the author's or authors' names are not used or if there is more than one reference to the same author or group of authors. All references to author should appear in the Bibliography and no references should be included which are not in the text. The style and exact punctuation used in the J.A.M.A. references is requested. For a journal this is: *Author's last name, initial, initial.: title of paper. Abbreviated name of journal, volume number: page, year.* Book references should give author, title, edition number, city, publisher and year.

Illustrations (photographs, tables and graphs) should be submitted separately and not combined in the text. There should be a separate sheet entitled "Illustrations" which contains the various types of illustrations listed separately and numbered in the order

Pork in the Human Dietary

PORK MAY be looked upon as an important factor in America's general health and well-being. The average intake of pork in America is about 46 pounds of lean pork and 20 pounds of bacon and salt pork per person each year.[1] But America's demand for pork goes further than taste appeal and deeper than mere statistics. Pork makes a valuable contribution to day-in-and-day-out nutrition.

Pork rates among the foremost sources of thiamine. As a source of all other B vitamins and many essential minerals, such as iron and phosphorus, pork meat is considered an important dietary constituent.

Lean pork is virtually completely digestible. Its protein serves to promote growth and aid in the maintenance of tissue cells. Like all high quality protein, that of pork aids in the elaboration of protein hormones, enzymes, and antibodies.

Pork constitutes a valuable part of the daily diet (Table I), and also contributes importantly to the nutrition of the pregnant woman (Table II).

Pork and pork products have won America's favor by their unique combination of economy, palatability, and nutritional value.

Sweet*10 a new cyclamate sweetener for sugar-restricted diets!

Sweet-10 can help many of your patients. Used in place of sugar, Sweet-10 is valuable in weight control and in low salt and sugar-free diets.

NON-NUTRITIVE SWEETENER
6 fluid ounces
Sweet*10
10 TIMES SWEETER
than sugar
To be used in place of sugar. Sweet-10 is a water solution of 17% cyclamate calcium, 0.1% Benzoic acid and 0.05% Methylparaben. Should be used only by persons who must restrict their intake of ordinary sweets.

Sweet-10's radio and newspaper promotion will suggest its use with coffee, tea, cereals and fruit or in cooked or baked foods. No calories . . . adds no weight.

Sweet-10's advantages over saccharin-type sweeteners will be stressed. Sweet-10 can be used in cooking, leaves no bitter aftertaste. *More economical than other cyclamate sweeteners.*

Sweet-10 is a water solution of 17% cyclamate calcium, 0.1% Benzoic acid and 0.05% Methylparaben. Also available in powder and tablet forms (cyclamate calcium). Now available in food stores.

Sweet*10 TIDY HOUSE PRODUCTS CO., Shenandoah, Iowa

in anxiety and tension states
. . . in hypertension

RAUDIXIN

Squibb Whole Root Rauwolfia

As a tranquilizing agent in office practice, Raudixin produces a calming effect, usually free of lethargy and hangover and without the loss of alertness often associated with barbiturate sedation. It does not significantly lower the blood pressure of normotensive patients.

In hypertension, Raudixin produces a gradual, sustained lowering of blood pressure. In addition, its mild bradycardic effect helps reduce the work load of the heart.

- **Less likely to produce depression**
- **Less likely to produce Parkinson-like symptoms**
- **Causes no liver dysfunction**
- **No serial blood counts necessary during maintenance therapy**
- Raudixin is not habit-forming; the hazard of overdosage is virtually absent. Tolerance and cumulation have not been reported.
- Raudixin supplies the *total* activity of the whole rauwolfia root, accurately standardized by a rigorous series of test methods. The total activity of Raudixin is not accounted for by its reserpine content alone.

Supply: 50 mg. and 100 mg. tablets, bottles of 100 and 1000.

GELATINE

Adequate nutrition during illness and convalescence is essential for recovery whether the patient is managed in the hospital or at home. In the latter case, physicians often must devote much time to instructing those responsible for caring for the sick in good nutritional practices.

"Meal Planning for the Sick and Convalescent" has been designed to relieve you of the need for repeating over and over again essential dietary facts. This new Knox booklet presents in layman's language the latest nutritional applications of proteins, vitamins and minerals, gives practical hints on serving food to adults and children, suggests ways to stimulate appetite and describes diets from clear liquid to full convalescent. Best of all it offers the homemaker for the first time detailed daily suggested menus for each type of diet, plus 14 pages of tested nourishing recipes.

If you would like copies of this new timesaving Knox booklet for your practice, use the coupon below.

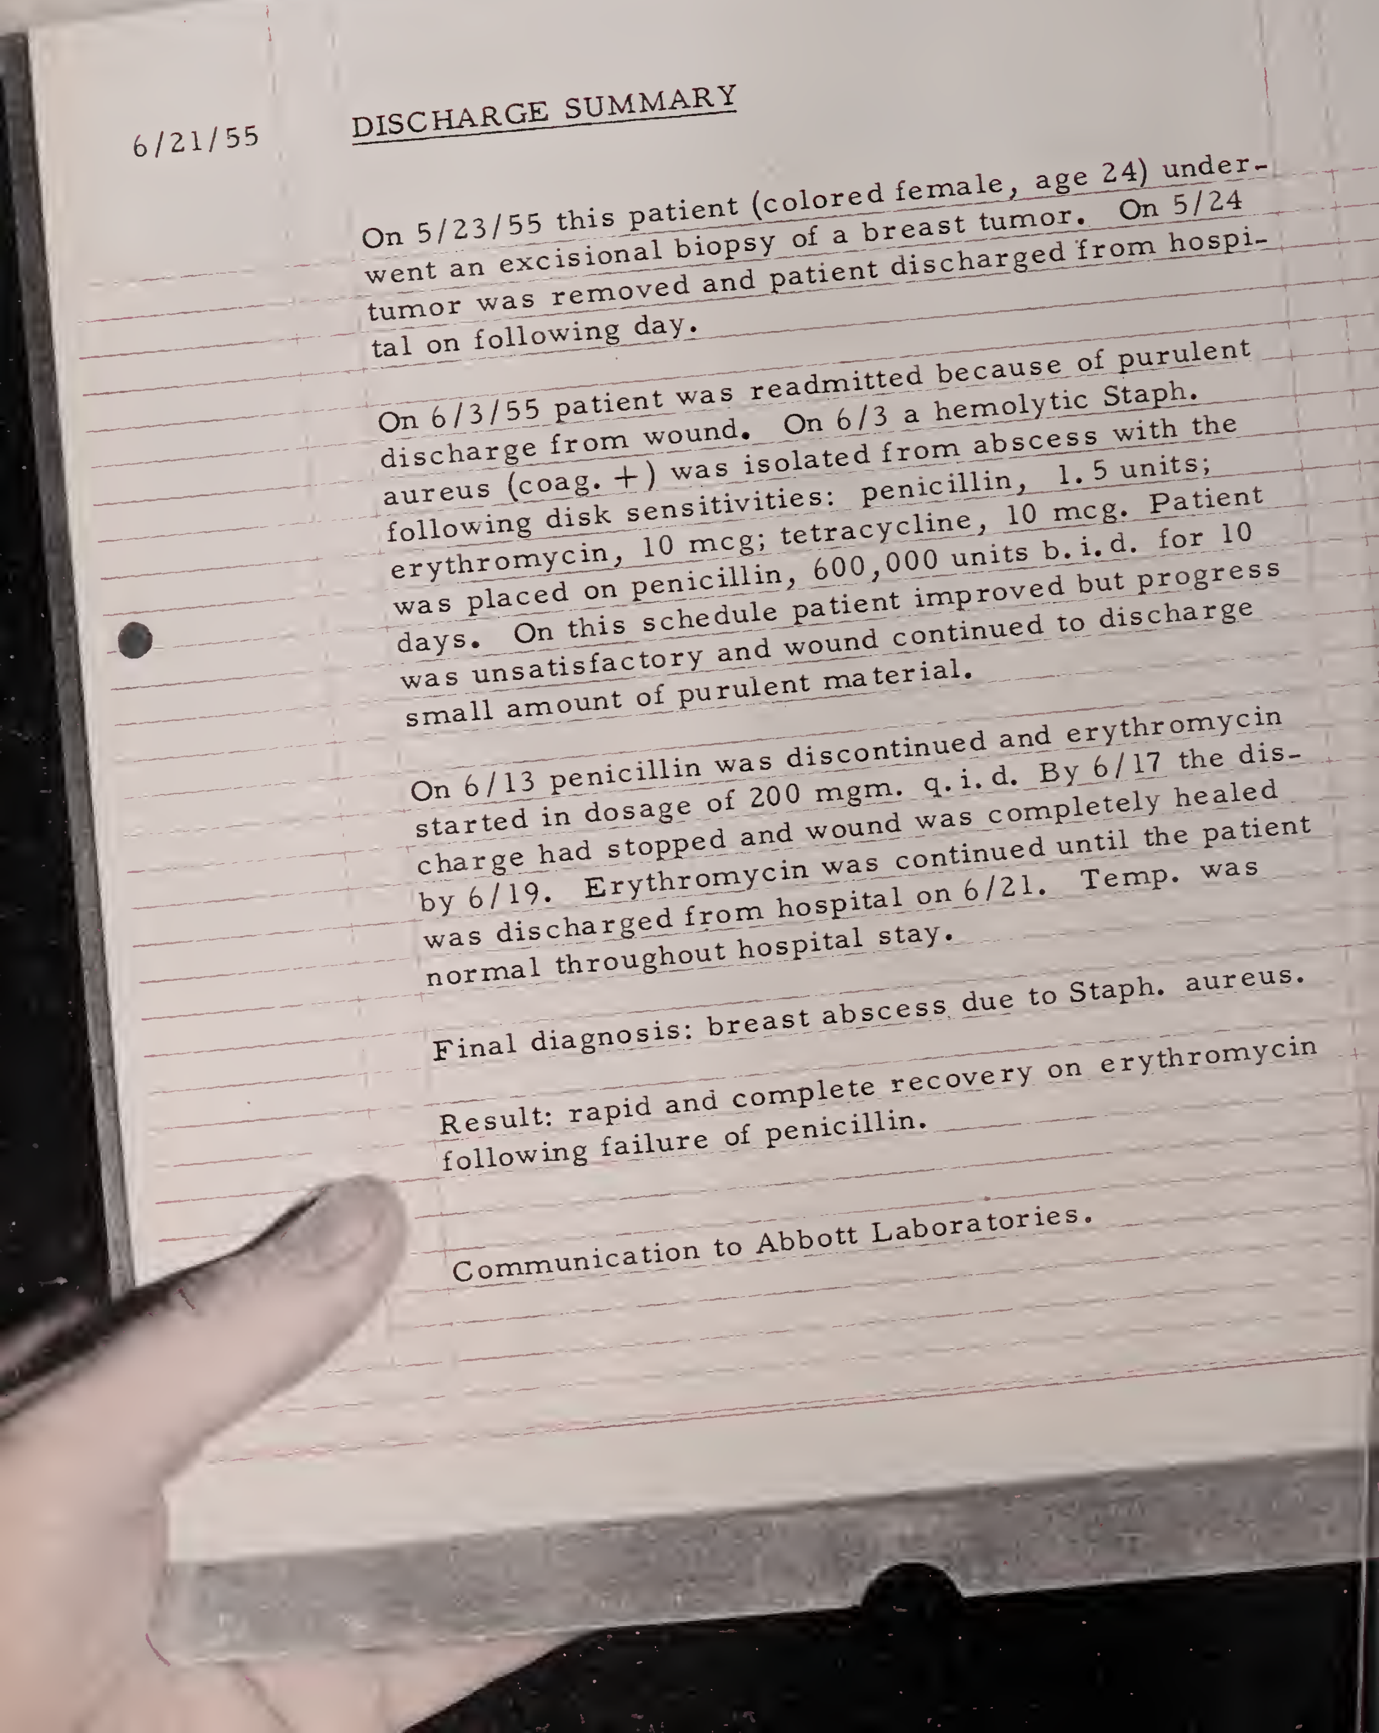
Erythromycin in treatment of abscess



6/21/55 DISCHARGE SUMMARY

On 5/23/55 this patient (colored female, age 24) underwent an excisional biopsy of a breast tumor. On 5/24 tumor was removed and patient discharged from hospital on following day.

On 6/3/55 patient was readmitted because of purulent discharge from wound. On 6/3 a hemolytic Staph. aureus (coag. +) was isolated from abscess with the following disk sensitivities: penicillin, 1.5 units; erythromycin, 10 mcg; tetracycline, 10 mcg. Patient was placed on penicillin, 600,000 units b.i.d. for 10 days. On this schedule patient improved but progress was unsatisfactory and wound continued to discharge small amount of purulent material.

On 6/13 penicillin was discontinued and erythromycin started in dosage of 200 mgm. q.i.d. By 6/17 the discharge had stopped and wound was completely healed by 6/19. Erythromycin was continued until the patient was discharged from hospital on 6/21. Temp. was normal throughout hospital stay.

Final diagnosis: breast abscess due to Staph. aureus.

Result: rapid and complete recovery on erythromycin following failure of penicillin.

Communication to Abbott Laboratories.

specific against coccic infections

Now, you can prescribe an antibiotic (*Filmtab* ERYTHROCIN) that provides *specific therapy* against staph-, strep- or pneumococci. Since these organisms cause most bacterial respiratory infections (and since they are the very organisms most sensitive to ERYTHROCIN) doesn't it make good sense to prescribe ERYTHROCIN when the infection is coccic?

filmtab®

Erythrocin®
(Erythromycin, Abbott)
STEARATE

with little risk of serious side effects

Since ERYTHROCIN is inactive against gram-negative organisms, it is less likely to alter intestinal flora—with an accompanying low incidence of side effects. Also, your patients seldom get the allergic reactions sometimes seen with penicillin. Or loss of accessory vitamins during ERYTHROCIN therapy. *Filmtab* ERYTHROCIN (100 and 250 mg.), bottles of 25 and 100.

HELP FOR PROBLEM DRINKERS *

* The Problem Drinker is one whose drinking causes a continuing and growing problem in any department of his life.

IF YOU HAVE PATIENTS IN THIS CATEGORY . . . . INVESTIGATE!

Hazelden is a non-profit organization, designed to help problem drinkers return to normal living. Its peaceful country setting is on beautiful Lake Chisago, near Center City, 45 miles northeast of the Twin Cities, with spacious grounds, suitable and well-equipped buildings. Hazelden is secluded, yet within easy reach of U. S. Highway 8.

Your Inspection Is Invited.

CLINICAL REVIEWS

Mayo Clinic and Mayo Foundation

April 9, 10 and 11, 1956

Rochester, Minnesota

This 3-day program will be devoted to lectures and discussions on problems of current interest in general medicine and surgery. The presentations will be made by staff members of the Mayo Clinic and the Mayo Foundation for Medical Education and Research.

The number of physicians who can be accommodated is necessarily limited. Those wishing to attend should communicate with Mr. R. C. Roesler, Mayo Clinic, Rochester, Minnesota.

There are no fees of any kind.

Now Available

7 Years Sickness Benefits

(HOUSE CONFINEMENT NOT REQUIRED)

Lifetime Accident Benefits

This extension of benefits is now available to you as a member of the Minnesota State Medical Association. Since December, *1947,* the inception date of our plan for members of your Association, the Caswell-Ross Agency has attempted at all times to secure for you the finest coverage in the accident and sickness field. These improvements will make your policy the best among many available to you. An application has been sent to you previously—why not complete and return it to our office now.

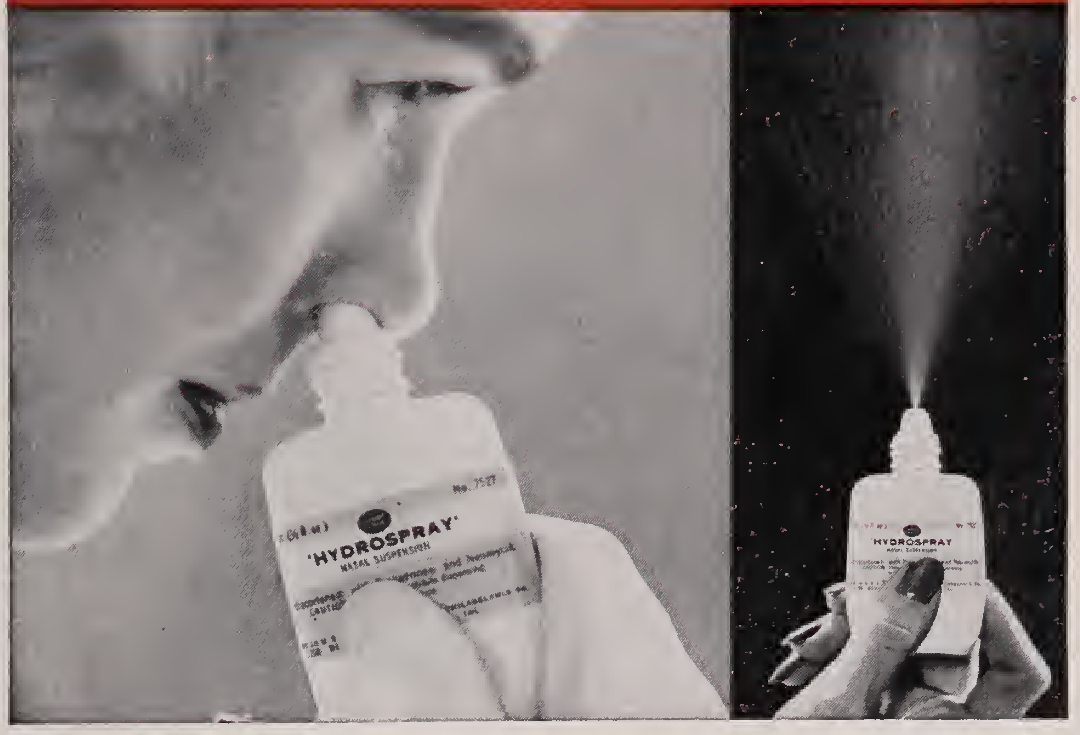
'Hydrospray' NASAL SUSPENSION

(HYDROCORTONE® WITH PROPADRINE® AND NEOMYCIN)

Anti-inflammatory—Decongestant—Antibacterial

MAJOR ADVANTAGES: New synergistic anti-inflammatory, decongestant and antibacterial formula. High steroid content assures effective response.



Topically applied hydrocortisone[1] in therapeutic concentrations has been shown to afford a significant degree of subjective and objective improvement in a high percentage of patients suffering from various types of rhinitis. HYDROSPRAY provides HYDROCORTONE in a concentration of 0.1% plus a safe but potent decongestant, PROPADRINE, and a wide-spectrum antibiotic, Neomycin, with low sensitization potential. This combination provides a three-fold attack on the physiologic and pathologic manifestations of nasal allergies which results in a degree of relief that is often greater and achieved faster than when any one of these agents is employed alone.

INDICATIONS: Acute and chronic rhinitis, vasomotor rhinitis, perennial rhinitis and polyposis.

SUPPLIED: In squeezable plastic spray bottles containing 15 cc. HYDROSPRAY, each cc. supplying 1 mg. of HYDROCORTONE, 15 mg. of PROPADRINE Hydrochloride and 5 mg. of Neomycin Sulfate (equivalent to 3.5 mg. of neomycin base).

New STEELINE Pediatric Table

Eases the burden of the physician's daily work

Includes built-in tare balance scale, built-in measuring rod, foam rubber cushion and electrical outlets with cord and plug—there are no accessories to buy. Top quality construction features include all-welded steel body, two roomy drawers and a large open compartment with shelf, providing easy, unhampered access to instruments and supplies. Front edge is protected from wear by a stainless steel baffle plate. Despite the fact that this new table has been designed to provide the physician with the best modern equipment, efficient modern production methods in our own factory permit us to keep the price well below that of comparable models. Write today for complete information.

Provides complete control of digitalis dose
Lilly
QUALITY / RESEARCH / INTEGRITY

'Crystodigin'

(CRYSTALLINE DIGITOXIN, LILLY)

. . . . permits accurate dosage titration to produce the maximum therapeutic effect

Since initial digitalization and maintenance dosage must be carefully individualized, 'Crystodigin' fulfills the important requirements of a preferred digitalis. 'Crystodigin' is a crystalline-pure, uniformly potent single glycoside that is completely absorbed in the gastro-intestinal tract. With 'Crystodigin,' the maximum therapeutic effect can be safely determined by dosage titration in increments as small as 0.025 mg.

Available in scored tablets of 0.05 mg. (orange), 0.1 mg. (pink), 0.15 mg. (yellow), and 0.2 mg. (white); and in 1-cc. and 10-cc. ampoules, 0.2 mg. per cc.

Surgical Treatment of Certain Congenital Cardiovascular Abnormalities in Infants and Children

PHILIP E. BERNATZ, M.D.,
JAMES W. DUSHANE, M.D.,
and JOHN W. KIRKLIN, M.D.
Rochester, Minnesota

IT is a universal human desire to insure the survival of children and enable them to progress normally to adulthood. It is unfortunate that the ravages of congenital heart disease have oftentimes prevented such a sequence of events. Until recent years, the physician's participation in the care of these children was necessarily directed toward palliation of symptoms and, in many cases, the accomplishment of even this palliation was accompanied by costly, recurrent hospitalization. Surgical correction of cardiovascular defects has changed the outlook for many of these youngsters from one of chronic illness to one of normal existence. We are deeply indebted to early investigators too numerous to mention, but special impetus has been given this surgery by men and women such as Gross, Crafoord, Brock, Potts, Taussig, Blalock, Lewis, Lillehei and Varco. Accomplishments in our institution and in others have been the result of remarkable co-operative enterprise stimulated by gratifying successes, but probably even more by repeated failures and apparently insoluble frustrations. Such integrated investigation has made it possible for us to speak to you about the successful surgical treatment of certain types of congenital heart disease in infants and children.

Report of Cases

The following cases illustrate causes for cardiac disability in infancy and childhood with some of the events leading to their surgical correction and return of these youngsters to a normal life.

Case 1.—After an uncomplicated prenatal course and delivery, this infant, who weighed 8 pounds, 4 ounces, at birth, was noted to breathe rapidly and to have tachycardia. The examining physician could not hear any heart murmur. X-ray examination of the thorax revealed cardiac enlargement. The child was lethargic and a persistent cough had developed. The family history was noncontributory. When seen at the Mayo Clinic, at the age of two and one-half months, the infant was noted to be well developed, without cyanosis but with a respiratory rate of 70 per minute and tachycardia measuring 168 per minute. The heart was enlarged; a palpable thrill was noted over the precordium and a systolic murmur maximal in the left fourth interspace. The second pulmonic sound was accentuated; femoral pulsations were good, and the electrocardiogram suggested biventricular hypertrophy. An x-ray examination of the thorax showed cardiac enlargement. The results of urinalysis were normal. The value for hemoglobin was 9.7 gm. per 100 cc. of blood and the results of other blood studies were normal.

Digitalization of the child resulted in partial abatement of the symptoms of congestive heart failure. Cardiac catheterization studies were done and revealed greatly elevated pressures in the right ventricle and pulmonary artery. A striking increase in oxygen content of blood from the pulmonary artery over that from the right ventricle was noted. Arterial oxygen studies gave normal results. On the basis of these studies a patent ductus arteriosus with a large shunt was concluded to be responsible for the child's congestive heart failure and surgical closure of the patent vessel was advised. At the time of operation, the diameter of the short patent ductus arteriosus exceeded that of the aorta, but division and closure were accomplished without incident.

The infant's postoperative course was uncomplicated. Cardiac enlargement receded and the administration of digitalis was discontinued after two weeks. The baby was recently seen at the age of one year, at which time he was noted to be a big, healthy child. Murmurs were not

---

Read at the meeting of the Southern Minnesota Medical Association, Albert Lea, Minnesota, September 12, 1955.

From the Section of Surgery and the Section of Pediatrics, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

heard and the size of the heart at this time was considered normal. This child now has a completely normal cardiovascular system and normal life expectancy.

Comment.—We are indebted to Gross for his successful closure of a patent ductus arteriosus in 1939. The case we have just presented is interesting in that congestive heart failure had developed within the first few weeks of the infant's life. A patent ductus is often well tolerated in childhood, but usually causes progressive trouble in ensuing years. The diagnosis of this abnormality may be relatively easy when the classical clinical picture is present. As in the case presented, however, the picture may be confusing and will tax the diagnostic acumen of all concerned with the problem. This infant presented a problem of congestive heart failure in the early weeks of life. We have learned that common causes of such a disability include patent ductus arteriosus, coarctation of the aorta, fetal endocardial sclerosis, ventricular septal defect and, rarely, atrial septal defect. We must always weigh carefully our plans for complicated diagnostic studies because even these carry some risk in these sick children. However, now that many congenital cardiovascular defects can be cured by surgical measures, and since the operative technic varies with each case, it is extremely important that an accurate preoperative assessment be made. Although cardiac catheterization studies are not necessary in most patients with patent ductus arteriosus, this case illustrates how valuable such studies can be. In addition to furnishing accurate information about location and size of shunts, such studies alert the surgeon to the presence of other abnormalities. For these reasons, the risk of cardiac catheterization in these sick infants can be justifiably assumed.

The surgical treatment of patent ductus arteriosus is very satisfactory. Ideally, surgeons prefer to operate on these patients when they are between the ages of three and ten years but, as in this child, indication for operation may be compelling at any time after birth. The results of such surgical treatment are extremely gratifying. Under ordinary circumstances, closure of the patent vessel can be accomplished with a risk of 2 per cent and we would recommend operation in practically all situations.

Case 2.—The mother of a girl who was first seen at the clinic at the age of six years stated that the child had been known to have a heart murmur since the age of six months. She was always behind the other children of her age, tired easily and had had intermittent bouts of fever but no cyanosis. For the next five years the child was seen at intervals and, except for some shortness of breath on exertion and intermittent bouts of fever, she made fairly satisfactory progress. She was, however, a very small, thin little girl. Cardiac catheterization was done at the age of ten years and these studies confirmed the presence of an atrial septal defect. It was concluded from the dye curves and saturation data that there was a left-to-right shunt of about 50 per cent of the child's blood flow. The roentgenogram of the thorax revealed cardiac enlargement and a shadow cast by a prominent pulmonary artery. Because of the cardiac enlargement, large shunt of blood flow and the presence of symptoms, closure of the atrial septal defect was advised. Surgical exploration revealed an atrial septal defect approximately 4 by 2 cm. in size. Though present in other regions, there was no septal remnant in the vicinity of the inferior vena cava orifice. The defect was closed, with a piece of polyvinyl-formal sponge (ivalon sponge), the exposure being by the atrial well technic proposed by Gross. The child's postoperative course was uneventful and when she was seen a year later she had gained 39 pounds and her exercise tolerance was normal. No murmur was heard and her general examination revealed nothing abnormal. Cardiac catheterization studies were reported 10 weeks postoperatively and indicated a normal cardiovascular system.

Comment.—Atrial septal defects are among the commonest congenital abnormalities of the heart. In 1875, Rokitansky presented a description of the types of atrial septal defects and provided a challenge for subsequent embryologic research. Through the years, any attempt to describe accurately the anatomic variations of these interatrial communications has been considered to be of academic interest only. As illustrated by the case we have just presented, however, operative repair of atrial septal defects is feasible and the problems of surgical repair demand a precise knowledge of the anatomic variants of interatrial communications. A classification of these communications has been presented previously,[1] but we would like to emphasize that the defect may involve any part of the interatrial septum. Depending on its size and position, there may or may not be a complete septal rim around the defect. Associated abnormalities of the heart may be present and common among these are congenital anomalous pulmonary venous connections of the lungs.

The diagnosis of an interatrial communication may be made on clinical grounds. However, study by cardiac catheterization is indicated for all patients whose condition is so diagnosed and who are being considered for operation, to aid in localization of the defect and in calculation of the total blood flow passing through the shunt. Associated anomalies of the heart also may be noted.

In the early phases of our surgical experience with this malformation, we advised operation only for patients with significant disability. Experience has shown the risk of operation to be surprisingly low, and in our series of 60 patients with atrial septal defects and left-to-right shunts who underwent operation, there have been three deaths, a mortality rate of 5 per cent. The results of closure of these defects are often dramatic.

At present, the evidence suggests strongly that the risk of operation is much less than the risk of keeping an atrial septal defect. For this reason, we advise operation in most cases.

Case 3.—A boy first seen at the clinic at the age of four years had been known to have a heart murmur since birth. He had always been dyspneic on slightest exertion and complained of frequent pains in his thorax. Cyanosis had never been noted. He could not keep up with other children and preferred games in which he could remain sitting. At the time of examination the boy was noted to be slender and pale. He was 42 inches tall and weighed 33 pounds. Precordial thrill was noted in the second interspace on the left and cardiac enlargement was demonstrated. A harsh, loud systolic murmur was heard in the pulmonic area. The second pulmonic sound was not audible. Along the left sternal border a diastolic murmur was heard which was not continuous with the systolic murmur. Peripheral arterial pulsations were normal. An electrocardiogram revealed right bundle-branch block and left ventricular hypertrophy. X-ray examination of the thorax showed evidence of a large heart with prominent pulmonary trunk segment and some increase in pulmonary markings. Cardiac catheterization was carried out and indicated the presence of pulmonary stenosis and ventricular septal defect. The right ventricular pressure was very high, approximately equal to the systemic pressure, but the shunt of blood flow was from left ventricle to right ventricle.

At operation a typical poststenotic dilation of the pulmonary artery was noted. The stenosed pulmonary valve could be felt through the wall of the pulmonary artery. A strong thrill was noted over the right ventricle. The child's circulation was then taken over by the extracorporeal pump-oxygenator system (Gibbon type). Through a right ventriculotomy incision, a very high ventricular septal defect, measuring about 2 by 1.2 cm., was found. The lesion was so high that it was considered most likely to be a form of partial, persistent, common atrioventricular canal with minimal involvement of the atrial septum. The ventricular defect was closed by means of a small piece of compressed ivalon sponge. The stenosed pulmonary valve was then opened under direct vision. The child tolerated the surgical procedure well and his postoperative course was satisfactory.

The child was seen three months after operation, at which time he had gained 4 pounds. His heart rate was 80. The parents had noticed a striking change in the boy in that he was very active, was happy and participated in the activities of the neighborhood.

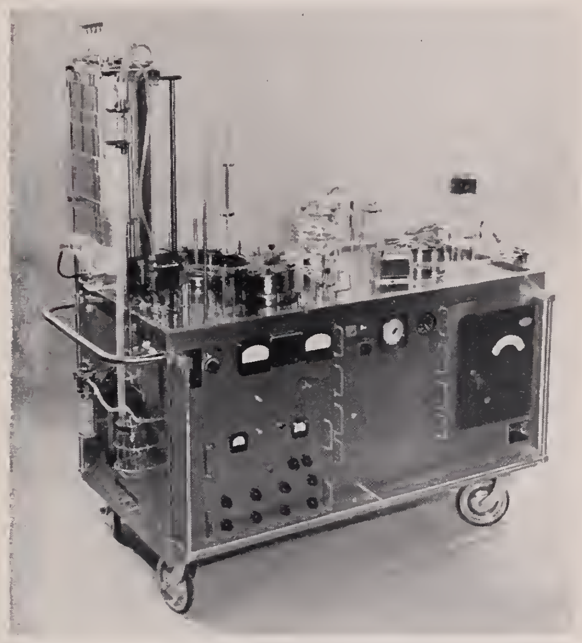

Fig. 1. The mechanical pump-oxygenator apparatus (Gibbon type) for temporary exclusion of the heart from the circulation.

Comment.—For many years it has been the dream of surgeons to be able to visualize intracardiac structures for a sufficient time to permit precise surgical correction of an abnormality, and a variety of methods have been utilized to attain this goal. Cases similar to the one just presented have furnished an urgent need for such surgical technique. The management of this patient with a ventricular septal defect is representative of a method of functional exclusion of the heart and lungs from the circulation of the patient, by means of a mechanical pump-oxygenator system. Other techniques of attaining this end have been employed by other investigators. We have been very pleased with the pump-oxygenator system of the Gibbon type (Figs. 1 and 2) and our clinical experience has been limited to this technique.

At the time this paper was written, twenty-six patients had been operated on by utilizing an extracorporeal circulation of the type described, and fourteen of them were patients with ventricular septal defect. Patients offered this operation to date have been those with symptoms of such severity that their prognosis was considered poor without surgical intervention. During the operative procedures the condition of the patients has been well maintained throughout the period of extracorporeal circulation. As a result, the ventricular septal defects have been visualized and accurately closed in an unhurried and precise manner. Of the fourteen patients with ventricular septal defect on whom this operative technique was used, ten are alive and well. Four patients have died in the postoperative period, but in no case could death be attributed directly to the period or method of perfusion. Actually, postoperative pulmonary complications have been present in all four cases in which death occurred and probably are related to the severe pulmonary hypertension that existed prior to operation.

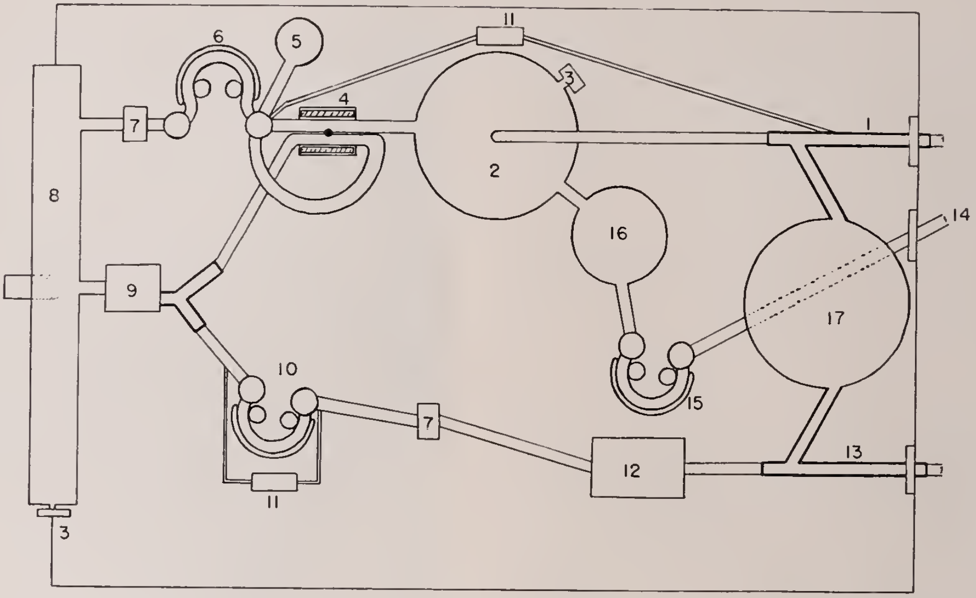

Fig. 2. Schematic representation of the pump-oxygenator system; (1) the venous-inflow line; (2) the venous reservoir; (3) level-sensing devices; (4) occluder; (5) input for the administration of blood and fluids; (6) recirculation pump; (7) high-pressure stops; (8) oxygenator; (9) holder for pH electrodes; (10) artery pump; (11) arterial and venous cuvette oximeter; (12) arterial filter; (13) arterial output to animal; (14) coronary-sinus inflow; (15) coronary-sinus pump; (16) coronary-sinus reservoir; (17) priming reservoir.

These surgical successes have demonstrated the value of the technique in which the pump-oxygenator apparatus is used for the treatment of certain cardiovascular abnormalities. This technique, which permits precise, unhurried intracardiac operation, is another valuable weapon for our attack on congenital heart disease. The risk imposed on the patient under these conditions has been reasonable and has encouraged the use of the technique in a greater variety of abnormalities of the heart and great vessels.

Summary

Patent ductus arteriosus, atrial septal defect and ventricular septal defect are three commonly encountered problems in the management of congenital heart disease in infancy and childhood. The evolution of surgical techniques has made it mandatory that accurate preoperative assessment of the defects be accomplished, and clinical evaluation plus cardiac catheterization studies have provided the surgeon with just such information. With early recognition and surgical treatment, the outlook for infants and children with certain abnormalities of the heart and great vessels has changed from that of chronic illness and recurrent hospitalization with short survival to that of normal life. The use of the extracorporeal pump-oxygenator system in a functional bypass of the heart and lungs enables us to attain that normal existence for more of these children. However, there undoubtedly will continue to be a place for the use of closed and semiopen surgical techniques in the treatment for certain cardiovascular abnormalities.

Causal and Preventive Aspects of Environmental Cancer

W. C. HUEPER, M.D.
Bethesda, Maryland

THE RAPID GROWTH and diversification of industrial activities and products have created during recent decades many new health hazards to producers and consumers, as well as to workers and the general public through occupational and environmental contact with industrial raw products, semifinished and finished goods, and waste products. Industrial and industry-related environmental cancers form an increasingly important segment of this new, artificial disease panorama associated with modern industrialism.

Industrial management and medicine have rather readily responded to the challenge of the relatively obvious acute and chronic toxic aspects of these new developments. They have been, on the other hand, much slower for various reasons in properly appreciating the serious nature and wide scope of the occupational and environmental cancer hazards also connected with industrialization.

General Considerations

A critical analysis of the general principles and special aspects of industry-related cancer-producing agents and cancers may, therefore, be helpful in placing this important problem into proper focus and in providing a constructive approach to a fuller understanding and awareness of and a more active interest in these health hazards which directly or indirectly concern not only industry proper but also industrialized human society as a whole. Industrial cancer hazards tend to spread from basic industries through processing and consuming industries to the general consumer, and may extend to the general population through the medium of environmental pollution of the air, water and soil with industrial wastes and environmental poisons possessing carcinogenic properties.

The discovery of an actual or even of a potential cancer hazard in an industrial establishment produces a serious and not infrequently costly problem to all branches of industrial management. The variety of aspects which arise and demand attention are summarized in Table I.

In addition to the various practical considerations and obligations which arise for industrial management from the discovery of an industrial cancer hazard, there ensue also definite moral duties toward the individuals who become exposed to carcinogenic material within or without the plant area. These are predicated on the fact that industry, like any other part of civilized human society, does not operate in a sociologic vacuum or as a self-contained entity but is an integral and interdependent part of modern mankind. Occupational cancer hazards and cancers, therefore, cannot be considered the sole concern of industrial management, while industry-related environmental cancers are definitely community, if not national, problems of public health.

This concept is based on the following factual evidence which clearly shows the medical-public health as well as economic implications of the existing situation. The number of reported cases of occupational cancers is considerably below the number of cases which have actually occurred. In fact, the great majority of occupational cancers which have occurred during the last two decades in American industries have not been made a matter of public record (Table II). To the number of recognized but unreported cases of occupational cancer must be added the not inconsiderable number of cases whose industrial origin remained for some reason obscure. To this group of occupational cancers doubtlessly belong almost all lesions which affected workers who were once employed and effectively exposed in a carcinogenic operation and in whom cancer developed after a latent period of many years while working for another employer and usually in a noncarcinogenic operation. Since the

labor turnover in many of these hazardous industrial operations is rather high, it stands to reason that this group of unrecognized occupational cancers is relatively large and that many of the workers affected by them ultimately become, with their families, wards of community, State and Federal welfare agencies.

Reliable observations made in Canada and in various European and Asiatic countries indicate that occupational cancer hazards exist in other industrial operations and occupations in addition to those mentioned in American reports. In fact, varying degrees of contact with known or strongly suspected occupational carcinogens exist for many industries and large worker groups for which, at present, no competent occupational cancer surveys are available, such as the rubber industry, steel and nonferrous-metal industries, dye and organic chemical as well as pharmaceutical industries, petroleum and coal-tar industries, textile industries, plastic, resin and paint industries, and the various branches of the transportation industry (railroads, trucking, aviation). There has been no worthwhile critical analysis made of the possible influence of the widespread use of the host of food additives, pesticides, sprays, detergents with and without dyes, cosmetics and drugs on

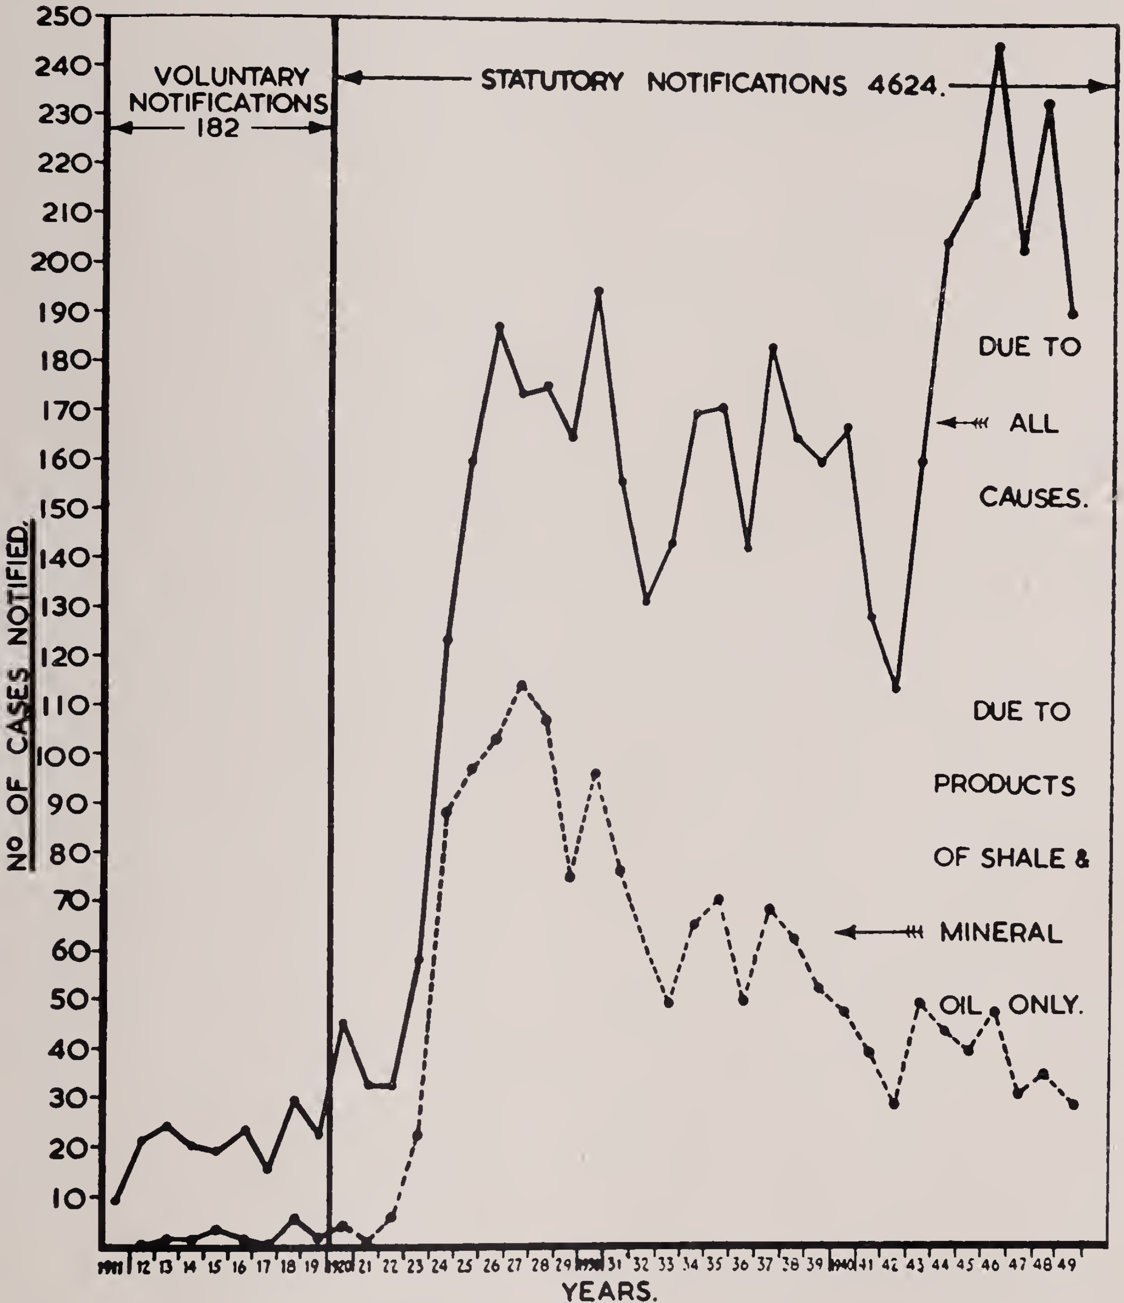

Fig. 1. Graph showing the number of cases of cutaneous carcinoma in male and female patients in England, Wales, and Scotland from 1911 to 1949, inclusive. Note the tremendous increase when reporting of cases was made statutory in 1920. The dotted portion of the graph denotes the number of cases contributed by shale oil and mineral oil only.

the environmental cancer panorama. It is only in recent years that pollution of the air, water and soil by industrial agents has seriously been considered as a possible cause of cancer.

It is mainly through this lack of proper awareness and reporting of existing and possible but unexplored environmental cancer hazards that the erroneous impression prevails in some circles that industry-related carcinogens are of minor importance, not only as an industrial health problem but also as a significant part of the general cancer problem. The introduction of statutory notification of all precancerous and cancerous lesions attributable to or suspected of occupational origin would greatly improve our highly defective epidemiologic records. The evident effectiveness of this procedure is strikingly demonstrated by a graph (Fig. 1) prepared by Henry[1] showing the number of cases of cutaneous carcinoma in male and female patients in England, Wales and Scotland notified before introduction of statutory notification and subsequent to it.

A second source of an incorrect evaluation of the importance of industrial cancers as an industrial health problem is related to the prevailing concept that these cancers contribute little to absenteeism. If the period of absence from work would be calculated not on the basis of the actual lifetime of the cancer victim but for his presumptive life expectancy, which is shortened by a precocious death from cancer, occupational cancers would acquire a much higher rating as causes of absenteeism than that with which they are charged at present.

It follows from these facts and considerations that industrial management and medicine are faced with several tasks for eliminating or containing industrial and industry-related, environmental cancer hazards and for devising means for preventing the future introduction of new ones. It seems to be wise and justified to discontinue the production and use of any agent which has been shown to cause cancer in man, if such an agent is not essential to human welfare and needs and, especially, if it does not serve any useful purpose. Any carcinogenic agent, even when essential and useful, should likewise be eliminated from the human environment, if an adequate noncarcinogenic substitute is available or can be developed and if the use of such a substitute is compatible with our present economic structure. Since a considerable part of the presently known industrial carcinogens forms an integral part of the products of our industrial economy and, therefore, cannot totally be eliminated, occupational and environmental exposure to them should be reduced by technologic methods to the lowest technically practicable level, because there is no reliable information available as to the minimal effective carcinogenic dose of any of the recognized industrial agents. Their degree of toxicity cannot be used as a guide in such matters, since there does not exist any parallelism between the toxic properties and the carcinogenic potency. It is well established, on the other hand, that the carcinogenic dose, as a rule, is well below the chronic toxic dose.

Industrial management and medicine would also be well advised to support the development of reliable and practicable chemical, physical or bio-assay screening procedures for the determination of potential carcinogenic qualities in existing and future chemical agents. The urgency of this appeal is attested by the fact that there exist a large number of chemicals capable of producing cancers in experimental animals and providing frequent and, in part, intensive contact, not only with large occupational groups but also with considerable portions of the general population. One American petroleum company, during recent years, has pioneered research on physicochemical methods for the discovery of carcinogenic oils. The demonstration of marked carcinogenic properties during chronic toxicity tests prevented the release of styryl 430 as a trypanocidal agent and of 2-acetylaminofluorene as an insecticide. On the basis of similar evidence, various chemicals employed in the processing, coloring and preservation of foodstuffs have been barred or removed from the list of permitted food additives in this country and abroad (thiourea, thioacetamide, butter yellow, dulcin, light green SF). The production and industrial use of 4-aminodiphenyl as a rubber and antioxidant were recently discontinued in England and the United States because this chemical produced bladder cancers in man and dogs and intestinal and breast cancers in rats. The manufacture of beta-naphthylamine has been stopped in England, Switzerland and Germany by the industries concerned without any legislative pressure.

While the evidence supplied by experiments on animals provides suggestive, but not conclusive, information on the potential carcinogenic action of a particular agent in man, these data, nevertheless, give distinct warnings as to the indiscriminate use of such agents in the human environment. The general principle has been adopted to consider any chemical, which is able to cause cancer in any species when given by any route and any dose, as carcinogenic to man until shown to be innocuous.

It is obvious that the complex nature of the occupational and industry-related cancer problem as well as of the execution of an effective control program necessitates close cooperation between industry and the medical profession. A recent statement by Dr. Curphey, chairman of the Council Committee on Public Health and Education of the Medical Society of the State of New York, may appropriately be cited in this connection:

> "The harmful effects of such agents could be reduced by encouraging free exchange of information and scientific knowledge between industries and the medical profession rather than by attempting to hide facts or by actively or passively resisting the efforts of outside scientific investigators because of the fear of facing legal responsibility for compensation of the diseased worker."[2]

Medical Aspects

The first and fundamental step for the institution of practicable and effective primary cancer prevention rests on the discovery and identification of the carcinogenic agents or the specific conditions of exposure associated with the development of cancers. Since Pott, in 1775, described the first occupational cancer—namely the scrotal cancer in chimney sweeps due to an exposure to coal soot, practicing physicians, especially internists, surgeons and industrial physicians, can claim exclusive credit for having advanced our knowledge in the field of industrial and industry-related cancers. During the last fifty years, their efforts have been particularly rewarding, because the great majority of industrial carcinogenic agents, carcinogenic industrial operations and cancers have been placed on record during this period. These developments may well serve as a stimulus to the medical profession to continue and intensify its efforts in this field, because epidemiologic data on the relative frequency of cancers of various sites available for different large and small worker groups indicate that evidently only a few of the actually existing industrial carcinogens have been recognized. The recently reported excessive frequency of cancer of the lung among English boiler scalers, grain dockers and iron-ore miners provides additional suggestive evidence in this direction. Observations of similar import relate to the excessive rates for lung cancer found among members of several circumscribed groups of workers having contact with various known respiratory carcinogens (Table III).

TABLE III. OCCUPATIONAL GROUPS WITH EXCESSIVE INCIDENCE OF LUNG CANCER

Occupational Group	Potential Respiratory Carcinogens
Metal workers, welders, metal grinders and polishers, wire makers, tool and die makers, foundry workers, metal moulders, lathe workers, etc.	Metal dust, lubricating oil mist
Cigar manufacturers and tobacconists	Tobacco dust, insecticides, soot
Engineers, mechanics, machinists, plumbers, etc.	Metal dust, soot, lubricating oil
Painters, decorators	Metal pigments, coal-tar dyes, carbon black, asphalt paints, solvents, vehicles (lacquers, resins, synthetic plastics).
Tar workers, road workers, asphalters, paviours, stokers, patent-fuel workers, furnace men, foundry laborers, rollers, etc.	Tar and pitch fumes and dust, soot

Industry-related factors most likely play a role in the recorded differences of mortality rates from cancer in different states of the United States, different parts of the same state, and between metropolitan areas and small towns. Additional evidence favoring an influence of industry-related factors on cancer frequency rates is derived from the recently observed rise in lung cancers and leukemia and the shift in age distribution of cancers of the skin into younger age groups of both male and female white patients.

Similar shifts into younger age groups are characteristic for many occupational cancers affecting different organs, including the skin. This development is in part due to the fact that the average latent period of occupational cancers is apparently shorter than that associated with cryptogenetic cancers because of the usually greater intensity of exposure prevailing under occupational conditions. Another factor influencing this shift in age distribution is apparently represented by the age at entrance into a carcinogenic occupation, since the age at manifestation of industrial cancers seems to be directly related to the age at entrance into the hazardous occupation.

Exposure times adequate for the production of occupational cancers vary markedly with the potency of a particular agent and the degree and route of contact with it. Additional factors of importance in this respect are the tendency of an agent to be retained over long periods within the body (depot effect), to be rapidly excreted or metabolically inactivated, or to produce permanent and significant alterations in the tissue constituents, even after a single brief exposure (ionizing radiation effect). The occurrence of leukemias among the survivors of the atomic-bomb explosions in Japan furnishes an example of the last-mentioned type of exposure time, while the long-delayed development of skin cancers in persons who have contact with certain petroleum products provides an illustration located on the other extreme of this scale.

To be effective, contact with occupational carcinogens does not need to be continuous; it is often intermittent and may cease many years before the appearance of the cancer. There are often no bridging symptoms connecting the changes which may develop during or soon after exposure to a carcinogen starts and those which may appear and precede or be associated with the subsequent delayed appearance of the cancer. Reliable observations indicate that the length of exposure time may be much shorter than the latent or preparatory period. It follows from these experiences that preventive measures, to be maximally effective, must be applied during the early part of the exposure period, if not before actual exposure starts. After an effective exposure once has taken place, local removal of any precancerous lesions affords, at best, a mild degree of protection and often does not prevent the ultimate development of cancer, even when continued contact with the carcinogenic agent was stopped with the first appearance of precancerous manifestations.

Some of the occupational cancers are associated with characteristic warning symptoms or precancerous lesions, such as melanoderma, leukoderma, hyperkeratosis, cutaneous atrophies, chronic dermatitis, warts and papillomas following exposure to coal-tar products, petroleum oils, shale oils, arsenicals, ultraviolet radiation and ionizing radiation, hemorrhages, angiectases, polyps and papillomas of the bladder mucosa after exposure to aromatic amines, leukopenic and leukemoid reaction following contact with benzol and ionizing radiation, chronic radiation periostitis and asbestosis, whereas other occupational cancers do not elicit symptoms which may serve as stigmas of carcinogenic exposure of specific types. Some occupational cancers develop from these benign hyperplastic and neoplastic precursor lesions, whereas others appear de novo within the exposed tissues. At times such developments appear to occur very rapidly from an organic matrix which seemed to be free from any abnormalities only a few months previously. Thus, relatively advanced cancers of the bladder have occasionally been seen in dye workers who seemed to have a normal bladder only six months previously on cystoscopic examination. Similar observations were made in regard to the appearance of lung cancers in chromate manufacturers having an apparently normal roentgenogram of the thorax six months previous to the discovery of a lung cancer of definite proportions.

Although such experiences do not represent the rule, they nevertheless show that medical examinations performed at six-month intervals do not provide a precautionary procedure guaranteeing an early discovery of occupational cancers. For this reason, it seems wise to perform periodic medical examinations at intervals shorter than six months, particularly in those exposed workers who are approaching the end of the usual latent period. It is obvious that only long-term workers are appreciably benefited by the limited protection afforded by periodic medical examinations. Workers who, after an effective exposure, leave a hazardous operation for other employment run an uncontrolled risk of cancer development unless they are properly warned as to the possibility of cancer formation during subsequent years.

Because of these and other difficulties in providing adequate protection against the development of occupational cancers by medical means, it is advisable to supplement medical measures with a selective employment policy. On the basis of existing industrial medical experience, Negroes have been found to be more resistant to the carcinogenic action of coal tar, petroleum oils and ultraviolet radiation than are white persons, especially those who are fair complexioned and freckled. Colored workers might best be selected for employment in operations in which contact with these carcinogenic agents is unavoidable. Considering the fact that the occurrence of bladder cancers in dye and rubber workers has been traced to the presence of carcinogenic chemicals excreted with the urine, persons who may have conditions which might interfere with an unimpeded excretion of urine, such as hypertrophy of the prostate, strictures of the urethra and ureters, renal stones, diverticula of the bladder and vaginal prolapse of the bladder, should be excluded from employment in operations having this cancer hazard. It does not seem to be wise to accept persons with chronic inflammatory conditions of the lung, such as bronchiectasis, for employment in work entailing contact with respiratory carcinogens. Whenever practicable, only older persons should be employed in carcinogenic operations, because even if an effective exposure should take place, there is a good chance that their normal life expectancy may not cover the average latent period.

Although the great majority of occupational cancers have occurred in men for reasons of employment of men in such operations, there is no valid evidence indicating that men are more susceptible to occupational cancers than are women. Female luminous-dial painters experienced osteogenic sarcomas and carcinomas of the nasal sinuses; cancer of the lung was only slightly less frequent among female asbestos workers than among male workers, while the entrance of female cotton spinners in English plants was followed by the appearance of cancers of the exposed skin and vulva among the female employees, who thus showed the anatomic equivalents to the scrotal cancers noted for many years among the male mule spinners.

Whenever occupational exposure to industrial carcinogens was intense and uncontrolled, these agents have demonstrated their high carcinogenic potency, which is reflected in the markedly elevated cancer attack rates found among the populations at risk. These observations suggest that cancer hazards may exist for susceptible individuals employed in operations in which the same carcinogenic exposures prevail in an attenuated form.

It can definitely be stated that chemicals which are carcinogenic in the industries of one country or in one particular industrial operation possess the same properties for the industries of another country and for other industries, provided that similar or identical conditions of exposure exist. The spread of occupational bladder cancers in dye workers through different countries approximately fifteen years after establishment of large-scale dye production provides a striking illustration of this dogma. It is also certain that agents which cause cancer in man when used for medicinal purposes, such as trivalent arsenicals, have the same effect when coming in contact with man as environmental carcinogens in the form of industrial water pollutants or as occupational carcinogens during the smelting of arsenic containing ores or during the production and use as insecticides. Conversely, agents which are carcinogenic in industrial operations, such as coal tars, shale oils or ultraviolet radiation, do not lose this property when employed for therapeutic purposes.

In the discovery and management of industrial-cancer hazards, proper appreciation must be given to the fact that the target organ or tissue for a particular carcinogen may vary with the route of primary contact and with the physicochemical status of the agent. Thus, the same industrial carcinogen may elicit cancers in different organs under differing conditions of exposure. Cutaneous contact with radioactive material results in carcinomas or sarcomas of the skin; ingestion may cause osteogenic sarcomas, intravenous injection may cause cancers of the liver or lung, inhalation of dust or gases may cause cancer of the nasal sinuses or lung, and total body exposure may cause leukemia.

Summary

The facts and considerations presented indicate that effective control of industrial and industry-related cancers depends on competent and harmonious teamwork among industrial management, industrial chemists, physicists, industrial engineers, sanitary engineers, physicians, workers and the general public. It will mainly be the task of the physician, for the time being, to be on the alert for occupational

(Continued on Page 22)

Problems in Clinical Diagnosis and Classification of Ventricular Hypertrophy in Adults

1. *Idiopathic Left Ventricular Hypertrophy*

BEN SOMMERS, M.D.
Saint Paul, Minnesota

CARDIAC enlargement has been recognized clinically and at postmortem for about 300 years.[1] The vast majority of cases of cardiac hypertrophy are associated with a recognized cardiovascular disease, such as hypertension, valvular disease or congenital heart disease. Nevertheless, there remain a small number with enlargement of obscure cause.

It is the purpose of this series of three papers to discuss three distinct types of cardiac hypertrophy occurring in adults and presenting difficult problems in diagnosis and classification. The three groups comprise instances of (1) predominant left ventricular hypertrophy, (2) isolated right ventricular hypertrophy and (3) the entity that has been designated as "familial cardiomegaly."

This first paper deals with two cases of left ventricular hypertrophy of unknown cause.

Report of Cases

Case 1.—A forty-year-old white man was seen in February, 1947, because of nocturnal dyspnea and orthopnea of six months' duration. When the patient was eight years old, a physician heard "extra beats," and "leakage of the heart" was suspected. Past illnesses included pneumonia at the age of twelve and right pleural effusion at twenty-five, requiring thoracenteses. In 1940, an inguinal hernia was repaired. He stated that his blood pressure had always been normal. In 1945, he was rejected by the Army, presumably because of cardiac enlargement. He drank large amounts of wine, on occasion consuming as much as one quart of muscatel during an evening. Nevertheless, he worked for the same company for nineteen years, starting as a manual laborer and later holding a responsible position as a machine operator. The family history failed to reveal evidence of cardiovascular disease.

Examination revealed a well-nourished, muscular man 73½ inches tall and weighing 206 pounds. His skin was sallow but showed no stigmata of vitamin deficiency. Funduscopic examinations, carried out several times during the three years he was studied, failed to show evidence of hypertensive changes or other abnormalities. Pertinent findings consisted of moderate abdominal obesity and cardiac enlargement. On percussion, the left ventricular border reached the left anterior axillary line in the sixth interspace. There were no murmurs. The aortic second sound was not accentuated. Heart tones were rather distant considering the patient's body build. The pulse was regular. Numerous determinations of blood pressure were normal on the initial and subsequent examinations. Systolic readings ranged from 140 to 128 mm. of mercury, with a diastolic range from 78 to 90. Usual levels were approximately 128/85. Blood pressure in the two arms was equal. Pulsations in the femoral and brachial arteries were normal. No evidence of congestive heart failure was found on the first examination.

The value for hemoglobin was 15 gm. per 100 cc. of blood (Sahli); erythrocytes numbered 5,100,000 per cubic millimeter of blood, and the leukocyte count was 8,950; a differential count was normal. The sedimentation rate was 10 mm. in one hour (Westergren); a Kline test gave negative results. The basal metabolic rate was minus 17 per cent. Serum cholesterol measured 295 mg. per 100 cc. Radiologic studies by means of fluoroscopy and 6 foot films revealed moderate left ventricular enlargement and slight right ventricular enlargement. Cardiac pulsations were normal. The electrocardiogram showed left axis shift, slight ST depression in standard lead I, and increased voltage of R in lead I and S in lead III.

Therapy consisted of a moderate weight reduction diet plus adequate supplements of vitamin B complex. Because of the slight elevation of serum cholesterol and the low basal rate, a therapeutic two-month trial of thyroid extract was given without benefit. Subsequent basal rates were all considered questionable because of the patient's claustrophobia.

To rule out antecedent hypertension, this patient's former physicians were contacted. Determinations of blood pressure at the age of twenty-five and again at thirty-three were available, as well as a few since that time; all were normal. Army records were unavailable. Coronary sclerosis was deemed unlikely because of the absence of angina pectoris, and myxedema and beriberi were ruled out by therapeutic trial.

From February, 1947, until his death in December, 1949, the patient ran a slowly progressive downhill course, although he was able to continue doing light work until January, 1949. Digitalization, a low-sodium diet and mercurial diuretics were needed to control left

Part I of thesis submitted for admission to the Minnesota Academy of Medicine, April, 1954.

heart failure. Rapid deterioration in his cardiac status occurred in January, 1949, with increase in cardiac size and beginning right heart failure. Dr. George E. Fahr saw the patient at this time and concurred in the diagnosis of left ventricular hypertrophy of unknown cause (Fig. 1). Prolonged periods of rest in bed were necessary in 1949 but did not halt the downward course. Auricular fibrillation and pulmonary infarction developed in November, 1949, when the patient was hospitalized. Death occurred in December, 1949, from congestive cardiac failure. The antemortem diagnosis was left ventricular hypertrophy of unknown cause.

Necropsy was performed by Dr. Kano Ikeda. The heart weighed 920 gm. The epicardial surface was smooth and glistening. There was gross dilatation of all the cardiac chambers. The myocardium of the left ventricle was 1.5 to 2 cm. in greatest thickness and was pale, cloudy and reddish brown, with no gross areas of fibrosis or infarction. A large mural thrombus 3 cm. in diameter was tightly adherent to the posterior wall of the left ventricle, interspersed among the papillary muscles. There were, likewise, multiple smaller mural thrombi scattered through the papillary musculature of the remainder of the left ventricle. The right ventricle was dilated and the wall measured up to 12 mm. in thickness. The valves showed no abnormalities. The pulmonary artery was markedly dilated. The root of the aorta showed a smooth intimal surface with only a very few streaks of subintimal atheromatous thickening. The coronary arteries were widely patent and freely pliable; they showed only a very slight amount of atheromatous thickening in their proximal portions.

Microscopic sections of the myocardium showed interstitial edema and hypertrophy of the muscle cells. The thrombus of the mural endocardium of the left ventricle exhibited organization. Microscopic study of the kidneys failed to show evidence of nephrosclerosis.

Other findings at necropsy were multiple pulmonary infarcts with pulmonary congestion and edema, chronic passive congestion of the liver and spleen, bilateral pleural effusion and ascites, multiple renal infarcts, and multiple petechiae and small ecchymotic areas involving the skeletal muscle, subcutaneous tissue and subserosal fat, as well as the areolar tissue of the mediastinum.

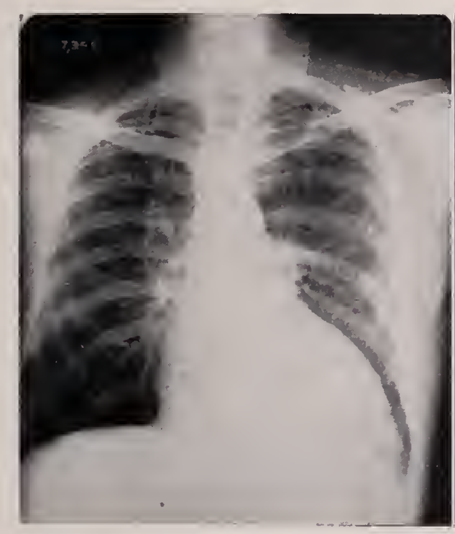

Fig. 1. (Case 1.) Thoracic roentgenogram taken in February, 1949, shortly after rapid deterioration of the cardiac status had occurred.

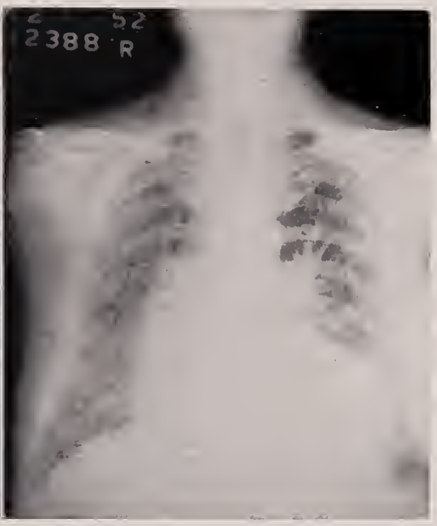

Fig. 2. (Case 2.) Thoracic roentgenogram shortly before death.

Case 2.—A fifty-five-year-old white man died in December, 1952, of congestive heart failure. Shortness of breath and constrictive thoracic pain on exertion had begun sixteen years previously following hemorrhoidectomy. At that time, an electrocardiogram showed complete left bundle-branch block. Digitalis was administered. Examination disclosed pronounced left ventricular hypertrophy, the x-ray silhouette being that of a boot-shaped heart (Fig. 2). One roentgenologist commented that it was unusual to have such minimal changes in the aortic arch as compared with the size of the heart. The blood pressure was normal on all examinations throughout the sixteen-year period preceding his death, usual readings being in the neighborhood of 120/80. In 1948, a pressure of 140/90 was obtained during a hospital admission for bronchitis. Heart murmurs were not heard, and the clinical diagnosis was coronary sclerosis with left ventricular enlargement, congestive heart failure and angina pectoris. Numerous physicians examined this patient during the course of his illness, and in 1951 he was examined at the Mayo Clinic, which reported normal blood pressure. Regular examinations had been performed for years, since the patient was a railway employe.

Necropsy was done by Drs. Kano Ikeda and C. Jarvis. The heart weighed 700 gm. The epicardial surface was smooth. The myocardium was flabby and light reddish brown. All chambers of the heart were markedly dilated. The right and left auricular appendages each contained moderately firm, reddish-brown thrombotic material. The remaining mural endocardium was smooth. The valves were normal. The coronary arteries were thin-walled, pliable and patent. A few scattered streaks of atheromatous thickening were present in the root of the aorta.

The aorta was smooth with the exception of a calcified atheromatous plaque located just above the bifurcation. There was no coarctation.

Microscopic sections of the heart showed small patches of fibrosis, myocardial edema and hypertrophy of the muscle fibers.

Sections of the kidney showed scattered foci of lymphoid-cell infiltration and a few hyalinized glomeruli. There was no evidence of nephrosclerosis.

The pathologic anatomic diagnoses were idiopathic hypertrophy of the heart with dilatation, mural thrombi in both auricular appendages, chronic passive congestion of the lungs and liver, old infarction of the kidneys, pulmonary edema and prostatic hypertrophy.

Comment

In 1901, Josserand and Gallavardin[2] were the first to describe idiopathic hypertrophy of the heart. Excellent reviews of the adult cases have been made by Levy and Von Glahn,[3,4] Levy and Rousselot,[5] and Norris and Pote.[6] Levy and Von Glahn reported ten cases of cardiac hypertrophy of unknown cause, eight in men and two in women. All were distinguished by a relatively short clinical course of from ten days to five years, without antecedent infection and with the primary symptoms of myocardial insufficiency. Angina was conspicuous by its absence (in contradistinction to our Case 2). At necropsy, all showed absence of advanced coronary sclerosis, but two cases showed extensive fibrosis. Necrosis of the heart muscle was present in four. A question thus arises whether the presence of fibrosis did not signify pre-existing myocarditis (if generalized) or coronary insufficiency (if mainly subendocardial). Myocarditis was also possibly implicated in two of the four cases reported by Norris and Pote.[6]

The possibility of antecedent hypertension has been explored by a number of investigators. Davis and Blumgart[7] stated:

> "To rule out the existence at any previous time of arterial hypertension is always difficult since fluctuations in blood pressure in this condition always render it theoretically possible that the blood pressure may have been elevated prior to the first recorded physical examination or between the various examinations listed."

Kaplan and associates[8] studied the arterioles of the kidney and adrenal in forty-three cases of congestive heart failure with predominant left ventricular hypertrophy of unknown origin and noted that 30.9 per cent had mild or severe renal arteriolosclerosis. Of 269 patients without hypertension, 12 per cent showed renal arteriolosclerosis that bore a relationship to their age. Of 154 patients with essential hypertension, 82.5 per cent dying in congestive cardiac failure showed renal arteriolosclerosis. These authors concluded that, although the role of antecedent hypertension cannot be excluded in the individual case of hypertrophy of the left ventricle of unknown cause, its absence in the majority of these cases seems likely. In a similar study, Ferris[9] found that renal and pancreatic arteriolosclerosis was present at necropsy in 40 per cent of fifty cases of left ventricular hypertrophy of undetermined cause.

Clawson,[10] on the other hand, has a different concept of the cause of this condition. Hypertension was absent in 5 per cent of his very large necropsy series of cases of "hypertensive" heart disease. If, however, a diastolic level of 90 mm. of mercury was chosen to separate hypertensive from nonhypertensive patients, very few remained in the nonhypertensive group.

Pertinent to the present discussion of possible etiologic factors in cardiac hypertrophy is the injury theory of hypertrophy, first propounded by Horvath[11] as early as 1897. According to this hypothesis, hypertrophy from whatever stimulus is due to stretching muscle fibers beyond the normal. Work and hypertrophy are both considered results of the stretching.[7]

Albrecht,[12] in 1903, described histologic evidence of muscle injury preceding hypertrophy and believed that hypertrophy was due to disturbance of normal cardiac nutritional requirements. Eyster's experiments[13,14] were most interesting and provocative. Aortic stenosis was produced by application of rubber bands in dogs until maximal dilatation resulted (usually on the third to sixth day). The bands were then removed in half the animals but allowed to remain in the other half. The hypertrophy that ultimately developed in both groups was comparable. Hypertrophy was considered a reaction to injury brought about by the sudden dilatation. Davis and Blumgart's work[7] on the relationship of coronary arteriosclerosis and congestive failure to cardiac hypertrophy favors the injury theory of Horvath. Little or no hypertrophy was present with lesser degrees of coronary sclerosis, but heart weights were considerably above normal in patients with coronary disease and congestive failure. Connolly and Littmann[15] confirmed this work and quoted Fulton's statement:[16] "This increased diastolic volume develops in toxic and inflammatory states and when the blood supply to the muscle is impaired." Further confirmation of the injury theory is found in the experimental production of hypertrophy in rabbits by Katz and associates[17] and by Hurwitz and Friedberg.[18]

Bell and Clawson,[19] Nathanson,[20] Levine,[21] Lisa and Ring[22] and others[23-25] deny the role of coronary sclerosis in the causation of cardiac hypertrophy. Gross and Lisa,[25] in a pathologic study of eighteen cases of left ventricular hypertrophy without a history of hypertension (material obtained from necropsy records alone) and with moderate to severe coronary sclerosis, found renal arteriolosclerosis in each case. They concluded that antecedent hypertension accounted for the cardiac hypertrophy.

The possible role of endocrine and neuroendocrine factors in the production of cardiac hypertrophy was discussed by Raab.[26] The occurrence of marked hypertrophy of the heart without hypertension in certain cases of acromegaly and the experimental production of cardiac hypertrophy in animals by the administration of growth hormone, thyroxin and desoxycorticosterone suggest neurohormonal influences in the causation of idiopathic cardiac hypertrophy.

Summary and Conclusions

Two cases of predominantly left ventricular hypertrophy have been described. Both patients were men forty-three and fifty-five years of age at death. Both died of congestive cardiac failure of three years and sixteen years' duration, respectively. The second patient had effort angina, and his electrocardiogram showed complete left bundle-branch block. A valid etiologic basis for the cardiac hypertrophy was not disclosed by clinical and necropsy studies.

The role of coronary sclerosis, antecedent hypertension and neuroendocrine factors has been discussed in the production of this type of cardiac enlargement. Although no definite conclusions have been reached, it seems wise, meanwhile, to avoid labeling as "hypertensive" those large hearts whose enlargement is of unknown cause. The term "idiopathic" is justified, serving as a stimulus to more profound study of these cases. Final solution of this problem awaits a more nearly complete understanding of the physiology and biochemistry of cardiac hypertrophy.

A Study of Ruptured Uteri

J. A. MALERICH, JR., M.D.
West Saint Paul, Minnesota

RUPTURED UTERUS is undoubtedly the most serious obstetrical complication encountered in medical practice. The present study of that complication was made at a private Minnesota hospital. Interest in the subject was fanned into activity by an unusual, thought-provoking circumstance. Four ruptures and one uterine rent took place between June and November, 1954.

TABLE I. REVIEW OF STATISTICAL STUDIES ON RUPTURED UTERI

Hospital	Period	Deliveries	Ruptured Uteri		Cesarean Section Rupture	Spontaneous Rupture	Traumatic Rupture
			No.	Incidence			
Private Minnesota	1944-1954	29,084	9	1:3232	67.0%	22.0%	11.0%
New York	1932-1946	111,753	57	1:1961	45.6%	36.8%	17.6%
Philadelphia County	1931-1941	318,103	105	1:3029	32.2%	25.1%	42.6%
New Orleans	1913-1950	127,522	96	1:1328	24.0%	30.2%	45.8%
Johns Hopkins	1920-1945	53,574	53	1:1010	18.8%	32.1%	49.1%

The above statement may give the impression of poor obstetrics, but the total statistics present a different story. These statistics cover the ten-year period from November 1944 to November 1954.

Table I compares four major studies of ruptured uteri with the present private hospital study. The classification of ruptured uteri is divided, for statistical purposes, into three groups. The largest is the post-cesarean section rupture group. Second, the traumatic rupture group, includes those ruptures caused by manipulative procedures and the use of pitocin. The third group is spontaneous rupture due to other (than the above) causes, such as great parity, multiple pregnancies, cervical tears.

The incidence of ruptured uteri to total deliveries is generally considered to be about 1:2000. This table presents the incidence of three groups: (1) charity hospitals—New York, New Orleans and Johns Hopkins; (2) the Minnesota private hospital; and (3) the combined private and charity hospital group of Philadelphia County. The implication is that private hospitals have a lower incidence of uterine rupture due to the smaller number of complicated cases. In our study, the incidence of uterine rupture was unusually low until the four ruptures occurred in the last five months of the study. With five ruptures, instead of nine, the incidence was 1:5400. Two thousand deliveries have occurred since the study, without rupture.

The frequency of post-cesarean section rupture has increased, and the frequency of traumatic rupture has decreased. It is noted in Table I that the four major studies and ours confirm this point. This has been a logical transition, over the years, because of the decreasing risk of abdominal delivery and the relative infrequency of the more difficult vaginal deliveries; such as, mid-forceps, high forceps, and version. The spontaneous rupture group, relatively unaffected by the uses of antibiotics and the changes in techniques, has maintained a constant frequency.

Table II presents first, the six post-cesarean section rupture cases. These six ruptures occurred among the 1,021 cesarean sections performed since 1944. Therefore, one in every 170 cesarean sections (0.58 per cent) ruptured. Since there were 29,084 deliveries and 1,021 sections, cesarean sections accounted for 3.5 per cent of the deliveries.

Two of the six cases ended in complete rupture. Both patients had previously had classical cesarean sections.

Four of these six cases ended in incomplete rupture. Two of the patients had had both lower and upper segment sections. One had had two classicals and one had had a single lower segment section. However, all three low segment sections were vertical, and two of these had had sections through the placental site.

TABLE II. CASE STATISTICS

Mrs.	Age	Gravida	Para	Types	Previous Sections	Gestation	Rupture
L.M.	31	6	3	Post Section	Classical	30 wks.	Complete
D.W.	41	2	1	Post Section	Classical	33 wks.	Complete
J.K.	27	2	1	Post Section	Vertical Low Segment	42 wks.	Incomplete
S.G.	23	3	2	Post Section	Classical	36 wks.	Incomplete
E.R.	33	3	3	Post Section	Classical Classical Vertical Low Segment	30 wks.	Incomplete
L.J.	33	3	2	Post Segment	Classical Vertical Low Segment	38 wks.	Incomplete
F.M.	36	6	5	Traumatic	0	42 wks.	Complete
D.D.	39	6	4	Spontaneous	0	40 wks.	Incomplete
M.H.	37	3	1	Spontaneous	0	41 wks.	Incomplete

No baby lived following complete rupture, but 75 per cent of the babies in the four incomplete rupture cases survived.

Both spontaneous rupture cases had incomplete ruptures into the left broad ligament with severe retroperitoneal hemorrhage.

Only one of the nine ruptured uteri, the case of Mrs. S. G., was amenable to repair. The rupture was small and at the lower part of the upper segment. This patient is now six months pregnant and hospitalized because of ruptured membranes.

Lastly, no case was in labor prior to rupture.

* * *

Rare and complicated cases appear common during the years of specialized training when on an active service. Private practice places the complicated case in its correct frequency. Yet, it is our duty, as private practitioners, to immediately diagnose and intelligently treat these rare complications. Therefore, it seems a review of our cases by groups would be of greatest interest here.

The largest group, spontaneous post-cesarean rupture, comprises six of our nine cases. It is acknowledged that this group is more readily diagnosed than the other types of rupture. It is also acknowledged that not all cases present classical signs and symptoms. Some are simply incidental findings at repeat cesarean sections.

Four of our cases had had histories of circumstances predisposing to uterine rupture and confirmatory signs and symptoms. Three of these had had febrile post-section courses and two had had sections through the placental site at previous abdominal deliveries.

Two of our cases were more complex. The first patient had congenital heart disease with superimposed subacute bacterial endocarditis. She had sudden severe low abdominal pain, nausea and vomiting, and vaginal bleeding at eight months' gestation. X-ray examination showed low placental insertion. The immediate diagnosis was rupture, but fear of the cardiac disability caused delay. Later a cardiologist cast doubt on the diagnosis by insisting that the marked hemoglobin drop was due to subacute bacterial endocarditis. After ten days' delay, the patient went to surgery. An incomplete chronic type of rupture was found, and the baby amazingly survived . . . as did the mother.

The most complicated case was that of Mrs. D.W., a forty-one-year-old para 1-0-0-1. She had a past history of peptic ulcer ten years previously, total thyroidectomy for hyperthyroidism, and classical section three years ago. Her pregnancy was normal up to her last office visit at thirty-two weeks' gestation. She was admitted to the hospital at 11:00 A.M., October 22, at thirty-four weeks' gestation, following sudden onset of coffee-ground emesis and colicky upper abdominal pain. She was pale, toxic looking, had peristaltic movements across a distended upper abdomen and a pulse of 110. Her uterus was eight months' size and cramping moderately. Fetal heart tones were heard in the right upper quadrant. An internist and a surgeon were called in, and their preliminary diagnosis was bleeding peptic ulcer. However, following confirmation by x-ray, small bowel obstruction was considered to be the diagnosis. Therefore, four hours after admission, the patient was taken to surgery. The abdomen was opened, and blood welled out. Instead of an obstructed bowel, the fetus and placenta were directly beneath the incision. The uterus was ruptured from 3 cm. below the bladder reflection through the fundus. The baby was stillborn. Hysterectomy was done.

Two ideas may be beneficially gleaned from the above cases. First, there is need of available and accurate past histories on all post-section patients. The anticipatory histories presented above were not completely obtained until after the emergency, and in some cases, were not obtained until the charts were reviewed for this study. Second, consultants are only a part of the "armamentarium" of the obstetrician. The former can advise only relative to his field. The obstetrician is the man best qualified to be responsible for the diagnosis and final disposition.

The traumatic rupture group has been distinctly diminished (4). As presented earlier, this is due partially to the increased use of the cesarean section and partially to the decreasing frequency of the more difficult vaginal deliveries. However, of those cases remaining, the diagnosis is just as puzzling and the treatment just as hazardous as before. Maternal and fetal mortality remains highest in this group.

One and one-half of our cases belong to traumatic rupture. The half case is that of a uterine rent. The rent was found at surgery, the second day postpartum, following the delivery of a stillborn. This grandmultipara had painless bleeding but no placenta previa, was stimulated with intravenous pitocin, and dilated with no abnormal contractions. After delivery, only moderate pressure was used to express the placenta. The postpartum course was stormy and identical to a fundal rupture. At surgery, 1300 cc. of blood and a 5-inch rent through the serosa into the muscularis were found. The cause??? . . . undetermined.

The true case of traumatic rupture is that of injudicious use of pitocin. This is an unpredictable drug. Many obstetricians have discontinued or greatly limited its prepartum and intrapartum use.

Mrs. F.M., a thirty-six-year-old gravida VI, had a history of five normal pregnancies, labors and deliveries. Now, again, at term and in early labor, she was admitted to the delivery section. Her progress was normal in spite of an exceptionally flabby uterus and extreme restlessness. She was prepared for delivery, and by 11:00 A.M. the head was 1 plus and dilation almost complete. However, the patient went into secondary inertia, and one minim of pitocin was given. In about five minutes, there was a sudden gush of blood, the patient became increasingly apprehensive, restless, and had air hunger. The fetal head went "way up." Version was elected, the patient anesthetized, and an unusually easy procedure accomplished the version. The patient came out of the anesthesia and appeared normal. However, about nine hours later, following increasing apprehension, abdominal pain and distention, she went into shock. She was taken to surgery, and a tremendous rupture from the anterior cervix to the fundus was found. Omentum filled the rent and only 200 cc. of blood were in the abdomen. Hysterectomy was done.

The last group is the spontaneous, nonsection, rupture group. Diagnosis seems most difficult in this group. First, all the possible extenuating signs and symptoms that occur in the other groups (classical and distorted signs, complete and incomplete ruptures, symptoms indicative of other pathologic conditions) can and do happen here. Add the difficulty of surprise, the lack of anticipation, and we have the crowning complication to diagnosis. Treatment also is thoroughly different and considerably more difficult in this group than in cesarean scar rupture.

Our problem case was Mrs. D.D., a thirty-nine-year-old gravida VI, para III. She was admitted at term following spontaneous rupture of membranes. Spontaneous contractions began at 9:00 P.M., and delivery occurred about three hours later at 11:54. An easy manual rotation, at low station and at complete dilation, was done from ODP to ODA. There was a slight gush of blood following the delivery of the head. The baby was slow to respond and attention was given him. About four minutes later, attention was returned to the patient. The placenta was delivered spontaneously and completely. Bleeding subsided, then became more profuse. Ergotrate was given intramuscularly, the uterus was massaged and lifted out of the pelvis. Intravenous ergotrate was given. Bleeding subsided again. Intravenous fluids had been ordered and were started at 12:20. Also, blood typing and cross matching had been ordered. The patient went into shock. Blood was not available until about forty-five minutes after it was ordered. It was then pumped in under pressure. In the interim, the cervix was observed to be intact, and the vagina was packed. In the excitement of the emergency, however, the uterine cavity was not explored manually. The packing seemed to control the bleeding for a time, and the patient's condition improved; but at no time did the systolic pressure reach 80 mm. Hg. Shortly, blood seeped through the packing, and hysterectomy was ordered. The clinical diagnosis was uterine rupture. Approximately two hours after delivery, the hysterectomy was completed but the patient was *in extremis* and expired. A large retroperitoneal incomplete rupture into the left broad ligament was found. Blood had dissected even as far as the kidneys.

Four major points are especially worthy of comment.

1. Bleeding in excess of 300 cc. is considered hemorrhage. Blood replacement must be ready for this loss — especially in the case of rupture. A minimum of 1000 cc. of type O Rh negative blood must be on hand in the delivery suite at all times. This is to be used until cross matching and typing can occur.

2. Whenever the bleeding is hemorrhagic, a patient shows shock, or a delivery has been done in which injury to the lower uterine seg-

ment could have occurred, the whole of the uterus, fundus and low segment, must be explored for lacerations, retained placenta, and membranes. The cervix must also be explored and inspected. These procedures are essential to establish the diagnosis.

3. Packing the uterus is such a controversial subject that it demands a separate paper. However, Gordon et al. consider it an obsolete treatment.[1] They consider that, worst of all, it gives a false sense of security, causes waste of time while the packing is saturating with blood, and more often than not fills the uterus with blood rather than making it contract. They do consider it useful in the single instance in which the patient cannot be immediately placed in the operating room. The opposite viewpoint—that there is a definite place for packing in the active treatment of ruptured uterus, is held by a number of investigators. Dr. Donald Frazer states, "Where rupture is confined to the lower uterine segment, packing, at times, can be used as definitive treatment."[4] In the case in which exploration does not present a tear, Brierton[5] suggests packing the uterus carefully and waiting to see if bleeding will recur.

4. The decision for hysterectomy is obviously a difficult one. However, when uterine exploration, as presented above, has confirmed the diagnosis, blood and more blood is given as needed, hysterectomy is the only answer. In the very severe cases, clamping the uterine vessels from below (vaginally) is advocated by some men. However, probably the most rapid and surest method of stopping this bleeding is to incise the abdomen (under local), retract the anterior abdominal wall and clamp the aorta above the biforcation. Dr. Kinsella[6] states that this can be done with rubber-tipped vessel forceps without damage to the aorta. He also states that this clamping can be maintained for approximately one hour. Following the clamping, there is ample time to replace the blood loss and bring the patient out of shock before proceeding with the necessary surgery.

In conclusion, I would advocate the use of teamwork. A team is a necessity. One man is needed to administer blood and intravenous fluids. Another is needed as an assistant in surgery. Besides these two, an anesthesiologist, a technician, two nurses and two aids will make up an excellent team. Everything must progress rapidly. A team can save time, show more care, and thus cut down maternal mortality.

Summary

1. Nine cases of rupture of the uterus have been reported. This represents the total number of ruptures occurring in a private hospital during the ten-year period from 1944 to 1954. In this time, 29,084 deliveries were accomplished.

2. Of these nine cases, six represented post-section ruptures, one traumatic rupture, and two spontaneous ruptures.

3. The fetal mortality was 50 per cent in the post-section rupture group. All the surviving babies belonged to the incomplete rupture segment of this group.

4. The post-section rupture group comprised 0.58 per cent of the 1,021 cesarean sections done in this hospital in the ten-year period.

5. There was one maternal mortality in the nine cases. This followed in the spontaneous rupture group.

6. These case studies should stress several important principles in diagnosis and treatment: (a) necessity of complete past histories on all previous cesarean section cases, (b) careful observation of these cases, prenatally and intrapartum, to detect the earliest signs of trouble, (c) exacting caution in the obstetric use of pitocin, (d) availability of 1000 cc. of Rh negative blood in the delivery suite, (d) following difficult vaginal labor or delivery, or any possibility of uterine rupture, intrauterine exploration (mandatory), (f) clamping the aorta, through an abdominal incision, suggested as a rapid method of controlling bleeding in severe cases of rupture, (g) necessity for teamwork in all cases of rupture.

Study of 200 Consecutive Patients Hospitalized for Asthma

LOUIS E. PRICKMAN, M.D.
ROBERT L. SOMMERVILLE, M.D.
and RODNEY D. STEINMETZ, M.D.
Rochester, Minnesota

THE records of 200 consecutive patients hospitalized because of asthma were surveyed to determine the types of asthma in which hospitalization was required, the role played by infection and allergy in these patients, and the extent to which cortisone and corticotropin (ACTH) had been used in treatment of their asthma. Another purpose was to direct attention to the importance of complete study of the asthmatic patient in addition to consideration of allergy and asthma alone.

Most patients who come to the Mayo Clinic for investigation of asthma do not require care in the hospital. Among the many reasons for hospitalization of patients having asthma are: (1) severity of symptoms, such as status asthmaticus, severe nocturnal asthma and orthopnea; (2) necessity for intravenous or inhalation therapy; (3) need for investigation that requires special equipment, anesthesia or bronchoscopy; (4) treatment of complications of asthma, such as sinusitis, and (5) preoperative and postoperative care of asthmatic patients who are undergoing various surgical procedures.

Results

These 200 consecutive patients had a total of 263 admissions to the hospital from January, 1952, to December, 1953, inclusive. The type of asthma in these patients was classified on the basis of history, physical examination and laboratory findings into three categories according to cause: namely, (1) allergic, or atopic; (2) intrinsic (asthmatic bronchitis) and (3) mixed. The history was of the greatest importance in differentiating the allergic and intrinsic types. Asthma due to bronchial obstruction by tumors and foreign bodies was not included in this study. Likewise, asthma secondary to congestive cardiac failure and certain chronic pulmonary diseases was excluded, although these conditions occurred in a few instances as complications.

The patients ranged in age from eleven months to eighty-six years; ninety-three patients (46.5 per cent) were in the age group from forty-one to sixty years and twenty-four (12 per cent) were twenty years of age or less. The sex distribution in each etiologic group, as well as in each age group, was essentially similar (Table I).

The asthma in the fifty patients classified in the mixed group (allergic factors plus intrinsic factors) was primarily allergic in six and primarily intrinsic in thirty-four; allergic and intrinsic factors appeared to be of equal importance in the remaining ten. Psychogenic or nervous factors were prominent in the perpetuation of asthma in thirteen patients of the mixed group.

As will be seen in Table II, the importance of studying the patient in entirety and not just the patient's problem of asthma, important as it may be, cannot be overemphasized. In only twenty-three patients was asthma the sole medical problem; in the remaining 177 patients, one or more diseases were coexistent.

A total of sixty-seven of these patients had received cortisone or corticotropin for their asthma before coming to the clinic; twenty-one of them required additional steroid treatment during their hospitalization here. Nineteen additional patients, not treated with steroid agents elsewhere, required cortisone or corticotropin for control of their asthma while under our care.

Comment

Patients who have intrinsic asthma are much more likely to require hospitalization than are

those whose asthma is due to allergy. Patients who have asthma as the result of contact with pollens occasionally are admitted to the hospital during the hay-fever season because of complications of asthma or because they must undergo some medical or surgical procedure. Such a patient is placed in an air-conditioned hospital room, if this is available. In the absence of air conditioning, a portable filter properly fitted to the window is entirely adequate to exclude pollen from the patient's room. Expensive air conditioning of a portion of a hospital for the care of asthmatic patients is not necessary or especially desirable. The patient who has asthma can be well cared for in the average clean hospital room provided certain simple precautions are taken.

The complications of asthma encountered in this series were all important and required special investigation and treatment. Among the most important were those of nasal and respiratory origin, as enumerated in Table II. A combination of asthma, nasal polyps and sensitivity to acetylsalicylic acid was noted in nineteen patients. As indicated in the same table, there were seventy-two instances of drug allergy requiring either treatment or precautions to avoid the drug to which the patient was sensitive. Since allergic reactions to drugs may be sudden, severe and even fatal, there should be on hand at all times a quickly available emergency kit containing sterilized syringes and epinephrine in a 1:1,000 solution, as well as aminophylline, 5 per cent solution of glucose, diphenhydramine hydrochloride (Benadryl) in doses of 50 mg. and hydrocortisone or corticotropin, all in solutions for intravenous use. Unless such emergencies are anticipated fully, much valuable time is lost in searching the hospital for the needed drugs. Oxygen and a BLB mask also should be quickly available.

The purpose of hospitalization of patients who have asthma is primarily to provide symptomatic relief and bring the asthma under control, so that the second and third objectives may be accomplished, namely to ascertain and to remove or treat the causes and the complications of asthma. Admittedly, these aims are not always accomplished but they are the patient's hope and should be the physician's goal. Great and valuable advances have been made in the development of remedies for relief of the symptoms of asthma, yet most patients with chronic asthma have had wide experience in their use and still have uncontrolled asthma. A great many asthmatic patients are taking steroids unwisely because of the symptomatic relief provided, little realizing that these hormonal agents in certain instances may do more harm than good.

The treatment of the 200 patients in this series for the most part was conservative. Symptomatic measures included rest, hydration, control of overcoughing, use of expectorants (usually iodides or ammonium chloride), administration of theophylline and use of epinephrine or related sympathomimetic preparations. Chemotherapy and administration of oxygen occasionally were necessary. Use of steroids was restricted to those patients whose asthma was inadequately controlled by conservative measures and in whom careful investigation revealed no contraindication to their use;

the hormonal agents were given in the shortest possible courses to combat the stress of severe or prolonged asthma. Many patients who had received steroids before admission experienced improvement on conservative management and often did not require additional exogenous hormonal therapy. All patients who had received either cortisone or corticotropin within six months and who had to undergo bronchoscopy, operations on sinuses or other surgical procedures were routinely prepared with steroids, the administration of which was continued for only a few days after operation.

Three deaths occurred in this series. One patient, who had intrinsic asthma, emphysema and recurrent bronchostenosis, died in status asthmaticus. The second had intrinsic asthma and died as the result of congestive cardiac failure secondary to cor pulmonale. The third patient, in whom the asthma was of mixed type, died after gastroenterostomy for a duodenal ulcer.

Summary

A study was made of 200 consecutive patients at the Mayo Clinic who were hospitalized for the treatment of asthma. The type of asthma was classified as intrinsic in 64 per cent of these patients, as allergic in 11 per cent and as mixed (both allergic and intrinsic) in 25 per cent. However, intrinsic factors were predominant in the latter group.

The complications most often encountered included nasal polyps, hay fever, vasomotor rhinitis, sinusitis, drug allergy, obstructive pneumonitis (bronchostenosis) and pulmonary emphysema. The triad of asthma, nasal polyps and sensitivity to acetylsalicylic acid occurred in nineteen patients.

The frequency of occurrence of a wide variety of accompanying conditions of clinical importance points up the necessity for a broad and thorough investigation of the patient beyond the study of the problem of the asthma alone. The occurrence of asthma uncomplicated by any other clinically important disease was noted in only twenty-three of these patients.

In most instances, conservative symptomatic treatment controlled the patient's asthma, but steroid therapy was resorted to in forty of the 200 patients. Steroid treatment was terminated as early as possible. Preoperative preparation with steroids was used in all instances when the patient had been given steroids within the previous six months.

The objectives in the hospital treatment of asthma are to provide symptomatic relief of symptoms and to search for the causes and complications of the patient's asthma, with removal of them when possible.

ENVIRONMENTAL CANCER

(Continued from Page 11)

cancers and, after their discovery, to provide for their early diagnosis and treatment and to further prophylaxis. The physician will be aided in these efforts by sanitary engineers and industrial chemists. The important task of primary prevention, on the other hand, does not belong to the medical domain but is reserved to the chemist, physicist and engineer. It is up to these members of the team to devise safe production and handling procedures, and, when necessary, to develop noncarcinogenic substitutes.

The degree of protection against industrial cancer hazards which can be attained with the full use of the available knowledge and facilities, however, depends also on the economic support which industrial management, labor, government and the general public are willing and capable to give to these efforts. It is safe to state that the conquest of environmental and industrial cancer hazards will be a gradual one and, in all probability, for many of these hazards only a partial one. It will resemble, in this respect, the pattern set in past decades by the successful containment of many infectious diseases. Success in this new fight will not come to us unless we know the facts and face them soberly and boldly.

The Prospect for Tuberculosis Control

S. MARX WHITE, M.D.
Minneapolis, Minnesota

THIS is not a statistical analysis. I shall confine myself to principles and practices.

The committee which met in 1904 and laid the foundation for the National Association for the Study and Prevention of Tuberculosis need not be named in its entirety, but the names of five of them will have a familiar ring: Drs. William Osler, Edward L. Trudeau, William H. Welch, Abraham Jacobi and Henry M. Bracken. It was in the following year, 1905, the year of the first annual meeting of the Association, that I had the privilege of attending with my chief, Dr. Frank F. Wesbrook, in Washington, D. C. I was elected the first Secretary of the Laboratory Section and served for one year. It would be invidious to pick out any one number of the original committee for special acclaim, but I can never forget the impression made by Trudeau. In his address, he said the meeting "means that through knowledge have come responsibility and hope, and through both, action." He at that time could only say for the Association: "It cannot but prove a *powerful instrument in the struggle against tuberculosis in this country.*"

In that day, diagnosis was by percussion and auscultation of the chest and the finding of swarms of acid-fast bacilli in the sputum. These methods were crude. It was rare to recognize the early stages of the disease before cavitation was well advanced. Most cases were overlooked until symptoms made their appearance, and we now know that this is very late.

As a diagnostic tool, using minute doses subcutaneously to produce a rise of temperature, Koch's tuberculin was still in use and had considerable value in early and suspected cases. As a student in 1896, Dr. Christian Fenger had found during an appendix operation on me, some mesenteric lymph nodes which he suspected were tuberculous. Dr. Frank Billings gave me an injection of tuberculin, the size or dosage of which I do not know. That it was larger than in later use, I do know. The shocking reaction, almost fatal, gave a temperature rise to within two-tenths of 107 degrees Fahrenheit. Tuberculosis has given me no manifestations since.

The diagnostic use of tuberculin by the conjunctival reactions of Calmette and Wolff-Eisner were announced in 1907. The cutaneous reaction of Clemens Von Pirquet was announced the same year but has been replaced by the more accurate technique of the Mantoux skin test. We remember, however, that Von Pirquet introduced the word "allergy."

Few people remember that Von Pirquet was appointed Professor of Pediatrics in the Medical School of the University of Minnesota. He remained here only a few weeks, then returned to Europe. He did not return to Minneapolis to assume his post. He was succeeded by Dr. Julius P. Sedgwick.

Treatment was not further advanced than was diagnosis. Rest, fresh air, and an abundance of good food were the only essentials except for remedies for cough and pain. Sleeping porches began to burgeon on the fronts, backs, and sides of urban houses. Cabins in the country blossomed as resorts for the "lungers." No effective drug treatment was known. Robert Koch's prediction made in 1890 that "much more important is its (tuberculin's) curative action," was already well on the way to disproof. A few like Osler recognized the value of morale.

In 1904, there were only about 9,000 beds for patients with tuberculosis, and these as a rule were in small and mere nursing homes—not hospitals. Trudeau's Sanatorium, a cottage type, was the leading institution in this country. With its laboratories, it later became the mecca for everyone who desired to prepare for the care of the tuberculous.

Public Health activity in tuberculosis was just beginning. Only two states, Maryland and New Hampshire, had tuberculosis commissions. The

---

Presented at the Spring Meeting of the Minnesota Society of Internal Medicine, Minnesota, May 21, 1955.

first municipal ordinances requiring the reporting of tuberculosis had been enacted in New York City in 1897 under the aegis of Dr. Herman M. Biggs. Public health nursing was in its pioneering stage. As for voluntary associations of citizens to oppose tuberculosis, only eight had any money or active programs in 1904. The first and foremost was the Philadelphia Society founded in 1902 under the leadership of Dr. Lawrence M. Flick.

The attack on bovine tuberculosis had just begun. Pennsylvania, in 1895, had established a State Livestock Sanitary Board to supervise the health of domestic animals. The Pennsylvania plan later became the model for other states. Tuberculosis in cattle has been virtually eliminated in this country. In man, tuberculosis of lymph glands—scrofula—and tuberculosis of the spine, both of bovine origin, have almost disappeared here. Elimination of the disease in cattle has been of incalculable value to agriculture, and yet many can remember the bitter fight by farmers, especially in a neighboring state, before success was achieved. It has been many years since I saw a fresh case of scrofula; yet within the year one has appeared, pointing up the fact that vigilance must never be relaxed.

In the days from 1910 to about 1930, when private sanatoria cared for many of our patients, the cost of sanatorium care was a heavy added burden. Then, too, a patient might and sometimes did get the idea that he or she was kept for the sake of the income to the institution. Dr. Coons of River Pines in Stevens Point, Wisconsin, one day at a meeting in Washington, D. C., asked me why he had so little trouble keeping my patients as long as needed when so many others left against advice. I told him then of my plan to counter this unfortunate circumstance. In the first interview, at which I told my patient the diagnosis and advised sanatorium care. I took time to outline the procedures and the prospect.

I said that the time for cure might be short or it might be long. If long, it wasn't the fault of the medical man but because of the disease. One difficulty was that many patients left the sanatorium before recovery was complete and consequently relapse would occur, with total loss of all the time already spent. If recovery were satisfactory, there would be a day when the physician would say, "Now I believe that by such a date you will be ready to go home. You may notify your family to be ready." Here is where the mistake can be made. No living person, not even the physician, knows the exact date at which recovery is so complete and sure that relapse will not occur. Remember this: You are not being kept in that bed because they need the income from it. There are other people waiting for that same bed. In order to buy insurance against a relapse, I want you to look the doctor straight in the eye and say, "Doctor, won't you let me stay another month?"

Except for some progress in collapse therapy, diagnosis and treatment remained in about the state outlined above until eight years ago. Some success in the drug treatment of tuberculosis became apparent in 1947 with the use of streptomycin.

The part played by the drug treatments under study at the present time has had a tremendous impact on the mind, public as well as professional. The tendency is to class the streptomycins, PAS, and isoniazid among "miracle drugs." Those who know the problem recognize these drugs as only a part of a very complex curative program and still consider rest, diet, regimen and all the ancillary procedures of paramount importance. We may recall that it was hoped that the brilliant researches of Ehrlich would result in the eradication of syphilis. Yet within the past decade or more, penicillin has proved more efficacious in syphilis than the arsenicals of Ehrlich. We may hope for more efficacious remedies in tuberculosis.

A temptation into which patients and physicians are falling is to consider the "miracle" drugs the providential answer to their need and to use them as primary factors in cure instead of as adjuncts. It is true that these medicaments have changed the outlook where the individual lesion is small and the invading pathogen can be reached by the drug, as in miliary tuberculosis, tuberculous meningitis, in some cases of renal tuberculosis and in some tuberculous sinuses. Where, however, dense masses exist, where cavitation is advanced and where the organisms cannot be so reached, the problem is distinctly different, and specialized skill in treating the whole patient over a long and trying time is needed. The proper use today of the drugs is to condition the organisms and tissues surrounding the lesion so that surgical removal can be accomplished. In 1953, in Glen Lake Sanatorium, 175 pulmonary resections—

segmental or subsegmental lobectomy or pneumonectomy—were performed with two deaths, a mortality of only 1.14 per cent. In 1954, 146 successful operations were performed without an operative death.

The favorable results of the new drug treatment in sanatoria has resulted in an insistent clamor for the use of the drugs in the home. Here the control and supervision are inadequate. Rest and food are not adequately controlled. More serious is the absence or inadequacy of rehabilitation, education, vocational guidance, occupational therapy and recreation. In Philadelphia and Cleveland, programs for home treatment by the new drugs are in operation. One views them with profound sympathy, for they are designed to supply the need of patients for whom there is not adequate provision for sanatorium beds. In Philadelphia, the program was begun on a limited basis on April 5, 1954, and later extended to cover the whole city.

A letter from the Chief of the Tuberculosis Control Section to Katherine Radabaugh Pearce under date of August 19, 1954, says, "In a very short time, it became apparent that there were serious defects in such a plan and that it was beginning to backfire on us to a certain extent." Details are not important here. Again, we must remember that the drugs are only an adjunct.

Very naturally, patients unaware of the fact or in their natural optimism unwilling to admit that the drugs are not a cure but only an adjunct, and relying on the glowing accounts in the public press, will choose to stay at home. They thus miss the real cure. It is my considered opinion that the physician, either the general practitioner or the internist not possessing long-time sanatorium training and facilities, should not allow himself to be drawn in by any importunity or circumstance to the home treatment of pulmonary tuberculosis by the new drugs now in our possession.

Reasons for this attitude may be stated briefly:

1. Even in the early case with the Mycobacterium in the sputum, it may take two or three months to convert from positive to negative with the elimination of the infectious state.

2. Too often the patient will cut his treatment short, either because he cannot afford to continue or because he does not believe it necessary to persist. The $15,000 which Perkins has estimated as the average cost of a case of pulmonary tuberculosis, together with the long-term reduction or absence of earning capacity, imposes a financial burden which few families or individuals can sustain. Even though hopefully begun, it has to be surrendered eventually with an impaired financial status hanging over the victim. It is in the public interest, therefore, that the community bear part or all of the expense in order that a cure may be wrought with restoration of the individual to productive earning capacity and to a non-infectious state.

3. Interruption or halting at any stage in the highly complex management is fatal to the complete success of the program. Without meticulous care and intimate knowledge of the processes of sensitization and immunity, the patient may be sensitized to the drugs. Without frequent studies in the laboratory, strains of the organism resistant to the drugs may develop. Immediate attention to these factors is necessary if catastrophe is to be avoided. The determination of types of anti-tuberculosis drugs, their combination and duration of use requires specialized knowledge on the part of the physician.

In a disease such as tuberculosis, where the advance or retreat of the malady is so slow, so insidious, and so masked, it requires constant supervision by skilled observers, trained in the field, to recognize the character of the changes going on.

This supervision must be continuous, uninterrupted and must operate for many years. After arrest of the disease appears to be complete, everyone—layman, social worker, physician—who has had an opportunity to study the progress of stabilization, of recovery, and of eventual return to self-support, has seen the catastrophies so readily occuring when mistakes are made because of inadequate supervision and control. To learn that after satisfactory recovery an economic recovery is also possible leads any competent person to aid the program in every way possible. Even though complete recovery may not be attainable in certain instances, the fact that plans properly organized for rehabilitation are in operation is of immense value as a morale builder. Medical staff supervision supplemented by rehabilitation, education, vocational guidance, occupational therapy, recreation and medical social service is the *sine qua non* of a successful attack on tuberculosis. The rehabilitation process should begin the moment the patient enters the sanatorium. It should be foremost in the plans for guidance of every patient whose recovery is possible.

It might be well, at this point, to consider for a moment the (1) recalcitrant, stubbornly defiant, and (2) the unco-operative patient.

1. The recalcitrant, stubbornly defiant group comprises alcoholics, which make up the majority, those with psychotic difficulties, and some of those sent in under compulsion by health authorities. These unfortunates can be and often are most prolific sources of spread of the infection, for they are defiant, reckless, without regard for others, and they defy all rules which would protect others as well as themselves. Kentucky state law now makes it a crime to expose others to communicable tuberculosis.

2. The unco-operative patient may be so because of an economic or family situation or from an emotional difficulty, such as depression, or simply ignorance. It should not be a matter for surprise that a well-ordered program for rehabilitation goes further than any other single factor in the treatment, to give courage, build morale, and secure co-operation.

Last May, while in London, I had an opportunity to discuss with Dr. R. R. Trail the Papworth Village and El Alamain rehabilitation projects. The principle in operation there is that the recovering and recovered tuberculosis victim spends the remainder of his or her life in these communities. Organization makes it possible for the community and its population to become self-supporting. Like some other segments of the British economy, such as general medical practice, this particular scheme may not be adapted to our economy. It does, however, point up the advantages of organization and supervision of rehabilitation.

In countries where civilization is advanced, as in our own, many infectious diseases are under fairly strict control. But note this: each has its specific method as in smallpox, plague, cholera, typhus, yellow fever and malaria. Those who live in advanced countries are outnumbered three to one by peoples living under conditions so primitive that disease still takes a terrific toll. Without the most extraordinary vigilance, victims and vectors of these diseases can be brought in by ship and by air in a few hours. No relaxation in the case-finding activities should be permitted; special attention should be given to groups and areas where the greater proportion of cases are found. All patients admitted to general and psychopathic hospitals; people in congested and poorly housed areas in cities; those in low income groups and in jails and on skid row; members of certain ethnic groups and transient labor groups, where the tuberculosis incidence is high—all need special attention.

I would like to outline, in the briefest form possible, the program which gives promise of success if faithfully carried out.

1. Find those harboring any trace of the disease. Here skin testing is the least expensive and can be used in mass form in schools, in industrial plants, in all sorts of organizations in districts and communities. Though less reliable, patch tests are less expensive than Mantoux, require less technically trained personnel and may be useful in certain groups. Follow-up of the positive cases leads to finding the infective case in the home, office or plant.

2. Intensify measures to find the infective case. Physicians still need to be taught to think of the disease in its early manifestations. Without chest x-ray, gastric washings, and in some situations bronchoscopy, the early minimal case may be missed. Mass x-ray surveys need to be speeded up and extended. Voluntary agencies have contributed immeasurably to this program, and its productiveness has been proved. Governmental agencies should now take a greater part.

3. When an infective case is found, prevent further spread of the disease from this source. Training the patient in the care of material discharged into the air is only partially effective. All sorts of failure occur. Isolation and care are the definitely effective measures. Here the sanatorium is the only final answer.

4. BCG vaccination of the nonreactors who are liable to unusual exposure—nurses and attendants in sanatoria and hospitals and others in any environment where a higher incidence of active tuberculosis is found. This should be voluntary. Early age is not a contraindication. Dr. Long states that "some of the most impressive results have been recorded in the vaccination of large groups of newborn infants."† A more highly protective vaccine may yet be found. Research for this continues.

---

†Esmund R. Long: Editorial. Ann. Int. Med., 41: 647-652 (September) 1954.

5. Research in all lines must continue—medical, social and economic. While governmental agencies may take part, the greater progress is made in the universities, the hospitals and sanatoria aided by funds provided by volunteer groups and individuals.

The cost of a case of tuberculosis has been estimated by Dr. James E. Perkins, Managing Director of the National Tuberculosis Association, to be about $15,000.* This includes medical care, compensation, pensions, relief payments and loss of wages but does not include the loss of potential future earnings. The reduction in time spent under the modern program will reduce this cost. In any case the cost is well repaid to the community when the patient is restored to productivity and is no longer a source of infection.

Although the program is not as yet completely stabilized or standardized, as of today the prospect of a cure in pulmonary tuberculosis is at hand. The definitive removal of the infective and infecting focus could not be thought of until the new anti-microbial remedies and the new methods of anesthesia and chest surgery had been developed. The program in each case is slow and requires infinite pains and skill—and a minimum of errors. The job before us is a difficult one and requires patient, unremitting labor. As we see it throughout the world, it seems an impossible one. As we come closer home, the results already achieved give us hope.

In St. Louis County, in Hennepin and Ramsey Counties, and in the State of Minnesota, elimination of infective tuberculous foci is going on at a rate never before achieved.

One task is to educate the law-making bodies of the profit to be secured to the citizens of Minnesota. Governmental agencies must be convinced of the social value of conquering tuberculosis. Tuberculosis Facilities Commissions have made recommendations to our Minnesota legislature calculated to use our present facilities to their fullest value. Halting advances have been made, but progress is disappointingly slow. Supporters of the program have not as yet exercised the pressure needful if the fullest use of even the present facilities is to be secured. Governmental bodies will respond only to popular demand. Voluntary agencies, including the medical profession, must enforce this demand.

Time alone will tell whether the new types of therapy, by which the cavitated and therefore infectious areas of lung are removed and the patient thereby relieved of his infecting tissue, are our final answer. The very promise leads many to relax their vigilance. Whether or not the answer is at hand, the need is for increased rather than lessened activity on the part of those interested in the welfare of the community.

---

*Perkins, James: The Stage is Set. National Tuberculosis Association.

REHABILITATION OF RECOVERED TUBERCULOSIS PATIENTS

"It's not what you are but what you may become that counts." This is the motto of the Minnesota Vocational Rehabilitation counselors. In addition to many other services, the counselors help prepare tuberculosis patients for normal, productive living.

"More than 50,000 men and women who have recovered from active tuberculosis have been trained for work and placed in a great variety of paying jobs by the State-Federal program for vocational rehabilitation since 1935," says a release from the Minnesota Tuberculosis and Health Association.

Minnesota Vocational Rehabilitation trained eighty-three recovered tuberculosis patients for jobs in 1954. Their estimated annual earnings were $220,312.

Recovered tuberculosis patients are often safer and more satisfactory employes and co-workers than those who have never been disabled. They have been taught to guard their health and report for regular tuberculosis check-ups. They are less likely to infect others than the apparently healthy person who does not receive regular medical examinations and who may have tuberculosis without knowing he is ill.

Employers have discovered that rehabilitated workers are absent from the job no more than workers who have no physical handicap. They do not jump from job to job. They have fewer disabling accidents on the job than do other employes.

"When a tuberculosis patient has properly recovered, received training, and is placed in the right job, he can do that job as well as anybody," the release concludes.

Seminar

BANTI'S SYNDROME

ANANDA S. PRASAD, M.D.
Minneapolis, Minnesota

THE term "splenic anemia" was introduced in 1866 to refer to cases of anemia in which the patient had splenomegaly but no frank evidence of leukemia. This term then obviously included cases of hemolytic anemia, aleukemic leukemia, Hodgkin's disease and several others, which were separated by Banti from the group of cases later known as Banti's syndrome.[1]

Review of Literature

Banti, in his earlier papers (1883, 1894, 1895, 1898, 1905, 1907) as cited by Reiff,[2] presented fifty cases with clinical and pathological findings, which were later grouped under "Banti's disease." The ages of the patients varied from twelve years to fifty-five years. The majority of the patients were close to thirty-five years of age. He stressed the fact that in these patients there was no evidence of any gastric disturbance, liver or biliary disease, malaria, lues or alcoholism. He described the clinical course as consisting of three stages—the first stage beginning with painless splenomegaly and the last stage characterized by cirrhosis and ascites. He also emphasized the fact that in earlier stages, no icterus, ascites or evidence of venous collateral circulation in the portal area was present.

He gave the hematological picture of eleven patients in whom he found hypochromic anemia and leukopenia. He stated, however, that erythrocytosis and normal leukocyte counts were found in some patients. He did a few bone marrow examinations which revealed hyperplastic marrow.

According to his descriptions, the spleen was invariably enlarged and he recorded 3000 gm. as the maximum weight. Adhesions between the spleen and the neighboring organs were noted. Typically, the cut surface of the spleen was firm and red, and small whitish knots, corresponding to malpighian follicles were seen. The capsule and the trabeculae were thickened. Thickening of the reticulum was marked so that it appeared almost homogenous or indistinctly fibrillar. This thickening was accompanied by narrowing of the interstices which eventually were reduced to minute cavities "dispersed in the sclerotic tissue." Because the lymph stroma retained its reticular or adenoid appearance, he termed this "fibroadenie." The sinuses were irregular and drawn together. A few follicles were described as normal but the rest contained periarterial rings of hyaline connective tissue. He found that initially follicular and pre-follicular segments were involved and later the extent of sclerotic zone progressed.

The liver, according to him, was involved in late stages and then it was indistinguishable from Laennec's cirrhosis. Changes in the gastrointestinal tract were secondary to cirrhosis.

He thought that an infectious agent was responsible for all these changes. He postulated that a toxin, elaborated either by the agent itself or as a product of altered splenic metabolism, spread through the splenic vein to the liver, thus accounting for the subsequent endophlebitis and cirrhosis.

He believed that the absence of icterus in the early stage, the large spleen in the presence of a grossly normal liver, and the fact that early splenectomy effected a cure were all evidences against cirrhosis being the cause of this condition.

He found that the spleens of patients with Laennec's cirrhosis showed congestion, dilatation of venous sinuses and absence of "fibroadenie" and that periarterial fibrosis was not marked, in contrast to the spleens of patients with "Banti's disease."

Development of interest in Banti's disease in

Dr. Prasad is a Medical Fellow, Department of Internal Medicine, University Hospital, Minneapolis, Minnesota.

From the Department of Internal Medicine, Veterans Administration Hospital, Minneapolis, and the University Hospital, Minneapolis, Minnesota.

Presented at the Medical Grand Rounds, Veterans Administration Hospital, Minneapolis, Minnesota.

America was due largely to two publications by Osler[23,24] in 1900 and 1902. He regarded conditions "to which an unusual number of labels have been attached" to be different stages of the same malady. Long duration, he thought, indicated a chronic toxic rather than an infectious process.

Warthin,[25] in 1904, published reports of two cases in which he was able to demonstrate portal obstruction leading to splenomegaly which resembled in all ways that of Banti's disease. Six years later, he collected from the literature all cases of portal obstruction and concluded that there was nothing in the clinical or pathological complex by which the cases of portal or splenic vein thrombosis could be separated from the cases of splenic anemia or Banti's disease.

Eppinger, in 1920 as cited by Reiff,[2] considered a long list of possible causes for portal obstruction. These included infections of the gastrointestinal tract or peritoneum; inflammation of the pancreas with fat necrosis, sometimes subsequent to syphilis; tuberculosis; puerperal sepsis or trauma; trauma to the vein itself; and compression or invasion of the vein by tumor. He considered primary portal thrombophlebitis, a condition similar in pathogenesis to atheromatous changes in the arteries, as a possible cause of thrombosis and obstruction, as well as primary liver disease, such as cirrhosis, terminating in obstruction of portal flow.

He studied twenty-three spleens removed surgically from patients thought to have Banti's syndrome on clinical grounds. He was unable, however, to demonstrate the histologic appearance described by Banti. He was also unable to observe the clinical stages which Banti described. He did report the case of an Albanian girl with splenomegaly which, according to him, satisfied all the clinical and pathological criteria for Banti's disease. That girl told him, before her death, that there were several persons like her in her country, suffering from the same disease. Partly due to this case and the girl's remarks, Eppinger concluded that Banti's disease had a geographic distribution and he did not deny its existence. He, however, thought that the splenomegaly resulting from portal obstruction was being incorrectly designated as Banti's disease.

Mennet,[26] in 1920, wrote that he was unable to find in Banti's description any change which did not occur in cirrhosis of the liver. Kauffmann,[27] in 1922, observed that the splenic sinuses were broadened in Laennec's cirrhosis and he thought that this was a specific difference between the spleen in cirrhosis and that in Banti's syndrome. Dürr[28] outlined a diagnostic triad for Banti's spleen which consisted of (1) sinus hyperplasia, (2) periarterial fibrosis and (3) "trabekela ufersplittering" which means modification of the architecture of the trabeculae. He noticed that from the irregular borders of these structures long tapering collagenous processes radiated into the pulp.

Naegeli[29] was unable to find any basis for distinguishing Banti's disease from ordinary cirrhosis of the liver. Klemperer[34] concluded from his own studies that the pathological picture produced by thrombosis of the portal vein was identical to that of Banti's disease.

Watson[30] studied the various forms of splenomegaly in 1929. He stated that the splenic sinuses in liver cirrhosis were wide and prominent in contrast to the narrow sinuses of primary splenic fibrosis or of splenic change secondary to known systemic disease.

Larrabee[31] believed that long continued passive congestion was the mechanism involved for splenic changes in Banti's disease.

Members of the spleen clinic of Presbyterian Hospital in New York[19,32,33] measured splenic vein pressure in eighteen patients with Banti's syndrome. The pressures ranged from 225 to 500 mm. of normal saline. The average was 363.5 mm. Obstruction was variously attributed to: (1) cirrhosis of the liver, (2) schistosomiasis, (3) thrombosis of the splenic vein, (4) cavernomatous transformation of the portal vein, (5) stenosis of portal vein and (6) undetermined causes. In their control group, which consisted of cases of hemolytic jaundice, Gaucher's disease, purpura, pancreatic adenoma, lymphoblastoma and splenomegaly of undetermined origin, the splenic vein pressure ranged between 70-360 mm. of normal saline, the average being 195.7 cm. The authors believed that a fundamental factor common to all cases of Banti's syndrome was portal venous obstruction.

Ravenna,[12] in 1943, proposed the theory that congestive splenomegaly is a result of primary lesions of the small splenic arteries which regulate the blood flow into the spleen (primary active congestion). He postulated that the regulatory power of the splenic arterioles is disturbed eliminating control over the inflow of blood and that the consequent congestive splenomegaly is the cause of circulatory disturbance in the portal bed.

Reiff,[2] in 1944, studied splenic sinuses by staining with azo-carmine. By this method he was able to distinguish the collapsed sinuses from bundles of collagen with fibroblastic nuclei. This distinction was impossible with hematoxylin and eosin or Dominici's stain. He thereby demonstrated that there was a marked increase of sinuses in the majority of spleens from patients with Banti's disease.

Wintrobe[1] believes that portal hypertension accounts for the development of Banti's syndrome. However, full acceptance of this view is difficult since an obstructive factor cannot be demonstrated in as many as 40 per cent of cases.[16] On the other hand, it is said that most of the time the site of obstruction is missed and overlooked.

Many animal experiments have failed to produce Banti's syndrome by partial or complete occlusion of the portal vein. However, when hepatic cirrhosis is produced in rabbits by manganese[20] or in dogs by means of silica[19] splenic enlargement and the picture of congestive splenomegaly develops. Probably an irritative factor also plays a rôle. It is possible that long standing portal obstruction rather than that caused by simple vascular occlusion is the important cause. Recently, Palmer et al[22] succeeded in producing splenomegaly, anemia, leukopenia and a mild thrombocytopenia in albino rats by intraperitoneal administration of methyl cellulose over a period of fifteen weeks. It is suggested that the syndrome produced by methyl cellulose may represent an experimental form of the process to which, in man, the term "secondary hypersplenism" has been applied.

Failure to demonstrate an obstructive factor in a number of cases and the fact that portal obstruction independent of splenic diseases has been observed in the absence of appreciable splenic enlargement support the concept that Banti's disease represents a primary disease of the spleen.

The concept of "hypersplenism" has been invoked to explain the hematological picture of Banti's disease.

A recent case report[6] concerns a child in whom umbilical sepsis developed and who later had multiple osteomyelitis and scattered subcutaneous abscesses (S. aureus). At the age of thirteen months, he had hematemesis. His spleen was very much enlarged. The liver was not enlarged. A splenectomy was performed and the pressure in the splenic vein was normal. The problem was whether the changes occurring in the liver and spleen had any relation to previous umbilical sepsis or whether the two processes were independent.

Recently, Banti's syndrome has been described, for the first time in veterinary literature[7] in a dog. On operation, they found an aneurysm of the splenic artery pressing on the vein, with splenic vein thrombosis, resulting in Banti's syndrome.

Tidy,[9] in a recent paper, stated that the size of the spleen has no influence on the anemia and leukopenia and that it is not the cause of hematemesis or of development of clinical cirrhosis and ascites. His conclusion was that the splenomegaly, the anemia and leukopenia and the cirrhosis develop independently of each other. If this is correct, there must be an agent which acts independently on the three structures.

McMichael[20] stated that the liver is always involved throughout the course, whether there is clinical evidence or not, and that the liver and spleen are both affected by the same factor but independently and not necessarily to the same extent.

Tidy, in 1952 as cited by Hauge,[11] advanced the theory that Banti's disease could be caused by RH incompatibility. Gerrard, however, believes that splenic enlargement could only be a rare sequel of RH isoimmunization. Recently, Banti's disease was recorded in two brothers but no blood group incompatibility was found in them.

Clinical Features

Most patients are under thirty-five, and symptoms may occur in childhood. In Banti's series, females predominated in a 2:1 ratio, but this has not been true in other series. Onset is usually insidious, but it may be sudden with hematemesis or melena. Gastrointestinal bleeding is present in 50 per cent of the cases. In other cases, there may be abdominal pain or discomfort or a left upper quadrant mass, or symptoms due to anemia may predominate. Flatulence, diarrhea, vague indigestion or even mild jaundice in association with abdominal pain and fever may appear. The spleen is usually big. The liver is moderately enlarged. Weight loss is not conspicuous. Anemia, which is normocytic, usually follows splenomegaly; however, after repeated hemorrhage it is hypochromic, microcytic in type. Cell fragility is normal or reduced in hypotonic saline solution. When cirrhosis is marked, the anemia may be macrocytic. Usually, there is leukopenia and thrombocytopenia. The bone marrow in early stages shows no abnormality. Limarzi[13] has reported myeloid hyperplasia in the earliest stages and maturation arrest of myeloid and megakaryocytic series later. In the presence of cirrhosis marked erythroid immaturity was found. Following hemorrhage, normoblastic hyperplasia is seen. Davidson[21] found achlorhydria in four of his eight patients.

The course of the disease may be prolonged and benign. However, at any time it may be interrupted by gastrointestinal hemorrhage, portomesenteric thrombosis or hepatitis. In other cases, there is a steady progression to hepatic insufficiency and signs of portal venous obstruction appear. Death is usually due to one of the complications mentioned above or an intercurrent unrelated disease.

In describing clinical features, Tidy[9] divided the patients into three different age groups: (1) those under ten years of age; (2) those between ten and twenty years; and (3) those in later decades. According to him, in the first group of cases, the hematemesis occurs when there is no enlargement of the spleen and no anemia, leaving hepatic cirrhosis as the only reasonable explanation. He indicated that the splenic enlargement is often not more than moderate; however, in three cases he found that the spleen extended down to the umbilicus. He stated that there is no relationship between the size of the spleen and subsequent prognosis, nor is there any between the prognosis and splenectomy. In two of his patients under eight years of age, the liver reached to the umbilicus, and in the third case it was easily palpable. According to him, the chance of survival up to twenty years in this group is very poor.

He described the second group of patients as having a less acute onset and course and a better prognosis. Hematemesis, in this group, is less fatal, and cirrhosis with ascites may be as common a cause of death.

In the last group, those patients in the later decades, there is splenomegaly with anemia and leukopenia. Hematemesis is not so serious and the duration may be many years with only minor disabilities.

From the above description, it seems that the changing picture may be produced by the same factor but of different grades of severity. Its effects are revealed by different structures as patients with the milder forms live on into adult life and the later decades. The severest grades cause death in early life, the brunt of the process falling on the liver and incidentally producing hematemesis in a body not yet possessing reserves of blood and of blood forming tissues. A less severe but still serious grade appears in adolescents and young adults. Mild grades in subjects who consequently survive into adult life have time to produce their action on the spleen and bone marrow. The hepatic lesions which are insufficient to produce early death are usually also insufficient to produce clinical manifestations of portal cirrhosis but are recognizable on pathological examination probably in every case.

Treatment

Anemia needs treatment. In cases of severe hemorrhage, blood transfusion may be required. Iron should be given in cases of hypochromic microcytic anemia. Splenectomy is a complex subject. At one time, this was considered the best treatment; however, conclusions were drawn without comparing results following splenectomy with the course of the disease in patients not operated upon. Immediate postoperative mortality has been reported as 10 to 38 per cent.[14] Subsequently, hemorrhage may recur in one-third to one-half of patients operated upon with the development of hepatic insufficiency or thrombosis in the portal area. In Howell's[15] comparison of fifty-one patients subjected to splenectomy and forty-three patients without splenectomy, no difference between the two groups could be demonstrated in regard to expectation of life, development of hepatic dysfunction, or occurrence of hematemesis.

However, studies at the spleen clinic at Presbyterian Hospital in New York[16,17,18] indicated that more careful selection of patients for splenectomy has resulted in better operative results. It has been stated that the surgeon should not perform splenectomy in Banti's syndrome unless he is prepared to do a splenorenal anastomosis as this may be the only opportunity to construct a satisfactory shunt. In general, abdominal exploration seems advisable in many cases of congestive splenomegaly.

A few contraindications for splenectomy have been suggested.[3] These are:

1. It is rarely justified in progressive decompensating liver disease.
2. It is not justified in the presence of a preoperative thrombocytosis.
3. It is not justified if bone marrow shows evidence of a toxic depression rather than the characteristic hyperplasia.
4. It is contraindicated in the presence of an erythroblastic bone marrow with a reversal of the myeloid-erythroid ratio.
5. It is contraindicated in children whose blood picture is not typical of this disease.
6. Lastly, a severe degree of anemia may also be an immediate contraindication for operation.

According to a recent article,[8] the following are considered as indicating serious operative risk for the porto-caval shunt procedure:

1. Plasma albumin below 3 gms.
2. Ascites which fails to respond to medical therapy.
3. Cephalin-cholesterol flocculation test results of 3 plus in 24 hours and 4 plus in 48 hours.
4. Prothrombin time prolonged more than four seconds above normal after adequate Vitamin K therapy.
5. Elevated serum bilirubin.
6. Bromsulfalein retention greater than 10 per cent in half an hour.

Several procedures are available for porto-caval shunt, the discussion of which is beyond the scope of this paper.

THREE-INJECTION METHOD FOR SALK VACCINE CONTINUED

A technical committee on the Salk poliomyelitis vaccine has agreed unanimously, and Department of HEW officials have concurred, that the present system of three injections should be continued. The group rejected a proposal for a single injection to get the limited supply to more children. PHS Surgeon General Scheele summed up for the committee in these words: "Although it is evident that the injection of 1 cc produces a marked degree of immunity, it was found that there is not enough scientific evidence on the duration of immunity after a single dose to lead to any recommendation for a change in the present dosage."

Accordingly, this remains the procedure: two injections, with the second following four to six weeks after the initial dose or as soon thereafter as possible; then a booster shot seven months or later after the second injection. Each shot 1 cc.

PHS's Poliomyelitis Surveillance Unit presented figures to the conferees on single injections which purported to show 69 per cent effectiveness in seven reporting states (of 1,490,459 children vaccinated in these states, only fifty-eight had paralytic polio, while of 1,789,651 unvaccinated children, 325 had paralytic polio). The states under study were New York, California, Colorado, Illinois, Maryland, Minnesota and Missouri. Dr. Jonas Salk, developer of the vaccine, demonstrated on the other hand that a second injection followed by the booster markedly increases the degree of immunity. In conclusion, the group of experts agreed to stand by the present system because, among other reasons, (1) a higher incidence of polio occurs in lower age groups and efforts should be concentrated there, and (2) difficulties possibly would arise in re-educating physicians and parents on any change.—*AMA Washington Letter*, Dec. 9, 1955.

Hematoma of the Retropharyngeal Space Causing Tracheal and Esophageal Obstruction

JOSIAH FULLER, M.D.,
FRANK J. HIRSCHBOECK, M.D.,
and ROBERT H. LABREE, M.D.
Duluth, Minnesota

THE retropharyngeal space frequently receives the attention of the endoscopist because it is the area first involved in mediastinitis following esophagoscopic perforation of the cervical esophagus. This potential space is described in Gray's anatomy[1] as being limited posteriorly by the prevertebral fascia, laterally by the investment of the carotid sheaths by the same fascia and anteriorly by the buccopharyngeal fascia covering the posterior aspect of the pharynx and the esophagus. It extends from the base of the skull down into the posterior mediastinum.

Although inflammatory involvement of this potential space is not uncommon, it is exceedingly rare to find it distended with blood. Spontaneous hemorrhage in the neck causing respiratory obstruction in hemophiliacs has been reported.[2,3] The following case report describes a patient with a post traumatic hematoma of the retropharyngeal space causing tracheal and esophageal obstruction.

Case Report

An eighty-two-year-old widow was admitted to the hospital because of acute dyspnea. The past history revealed that for eight years, the patient had been under care because of chronic heart failure with recurrent attacks of myocardial insufficiency due to generalized arteriosclerosis with mild hypertension, 150/100. During the period of continuous observation, she was treated with digitalis, a low sodium diet and ammonium chloride. Because of failure to follow all therapeutic injunctions, the patient occasionally had need of additional dehydration with a mercurial diuretic. Except for stasis ulcers of the left leg due to chronic venous insufficiency, no other significant illness was found in the previous medical history.

The patient stated that about twenty hours previous to admission to the hospital, she fell at home. This caused no apparent difficulty until about seven hours before admission when she began to have pain in the left side of her neck. Two hours before admission, she noted onset of swelling in her neck which rapidly increased in severity and was associated with respiratory difficulty. The examination in the emergency room revealed an elderly woman in severe respiratory distress. There was marked inspiratory stridor and in order to have any airway, she had to sit up straight with her chin thrown forward. There were also multiple bruises over the front and back of her trunk. The tense swelling in her neck extended laterally to both sternocleidomastoid muscles and from her chin to her clavicles.

X-ray of the cervical spine failed to reveal a fracture but the lateral film showed a very marked widening of the retropharyngeal space (Fig. 1). Because of the history of a recent fall and the tenseness of the swelling, this was assumed to be due to hemorrhage. However, the immediate problem was the necessity for establishment of an airway. A tracheotomy was done with prompt relief of her respiratory distress. After this, it was apparent that the patient was unable to swallow. Liquids would not pass down and attempts at passing a stomach tube met an obstruction in the lower pharynx. It was possible to see the hematoma bulging through the posterior pharyngeal wall.

The patient's fluid and electrolyte balance was maintained intravenously for a few days. Hematologic evaluation failed to reveal any abnormality of the clotting mechanism. Although it was apparent that the active bleeding had stopped, there was a steady extension of the cervical ecchymosis to involve the chest, breasts and trunk. A film taken at this time revealed that the hematoma was smaller (Fig. 2). However, it was apparent that there would be many days before this blood clot would become small enough to allow her to swallow. Therefore, nine days after admission, a left anterior cervical mediastinotomy was performed. This was done in the usual manner through an incision along the anterior border of the sternocleidomastoid muscle. The dissection was carried through the deep fascia above the omohyoid muscle, medial to the carotid sheath and lateral to the thyroid gland. The buccopharyngeal fascia was tense and bulging. Beneath this fascia was found a space containing an estimated 300 cc. of clotted blood. After the hematoma was evacuated, it was possible to palpate up into the pharynx behind the posterior pharyngeal wall and down into the mediastinum behind the esophagus.

After the mediastinotomy, the patient made slow but steady improvement. The tracheotomy tube was removed two days later and she was dismissed from the hospital ten days after that. An x-ray film taken five days after the mediastinotomy revealed a marked reduction in the

---

From the Department of Surgery and Internal Medicine of the Duluth Clinic.

width of the retropharyngeal space (Fig. 3). The patient's subsequent course was uneventful and she was able to swallow all types of food without difficulty.

Attempts at explaining the source of this hemorrhage are purely speculative. If attention is directed to the illustrations, one may note the scattered calcifications about the neck. It can be assumed that some of these calcifications are in her markedly arteriosclerotic blood vessels. It is conceivable that torsion on one of these pipe-stem vessels during the fall caused a fracture of the vessel wall and the subsequent hemorrhage.

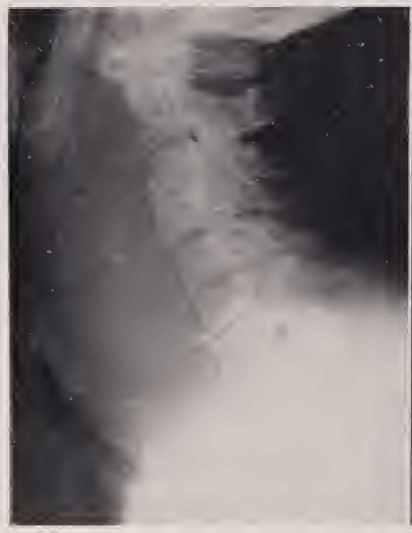

Fig. 1. Lateral view of neck taken on admission, showing marked widening of the retropharyngeal space.

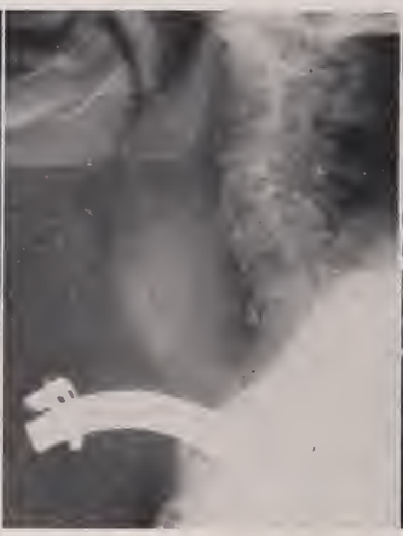

Fig. 2. Lateral film of neck taken eight days after admission. There has been some decrease in the width of the retropharyngeal space. Tracheotomy tube is in place.

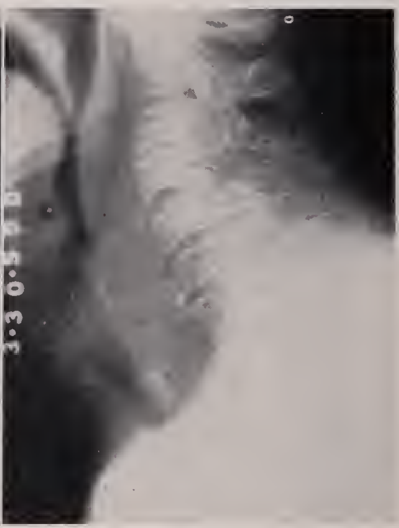

Fig. 3. Lateral film of neck taken five days after anterior cervical mediastinotomy. Tracheotomy tube has been removed and there is reduction in the width of the retropharyngeal space.

Summary

A case is reported in which an eighty-two-year-old woman in chronic congestive heart failure developed, following a fall, tracheal and esophageal obstruction from a hematoma in the retropharyngeal space. The patient was treated successfully by an emergency tracheotomy and a later anterior cervical mediastinotomy.

STUDY OF THYROID HORMONE

Three major diagnostic laboratory methods are available in the estimation of thyroid activity, said Dr. Keith P. Russell, Assistant Clinical Professor of Obstetrics and Gynecology, University of Southern California, speaking before the Fourth Annual Clinical Meeting of The American Academy of Obstetrics and Gynecology held in Chicago in December. Dr. Russell said that the PBI Test (protein-bound iodine) of the serum or plasma has been shown to be an accurate index of circulating thyroid hormone, and at present is the most widely used single test of thyroid function. The PBI Test measures the amount of the hormone (thyroxine) being put out by the gland.

Dr. Russell described the radioactive iodine test (I 131), as the test that measures the functional capability of the gland itself. The third and last method described was the basal metabolic rate (BMR), which measures the effect of thyroxine on the metabolic function of the patient's cells, its action on the body tissues.

Dr. Russell summed up the three methods by concluding that each one measures a different facet of the total function. Therefore, all three are of major importance in the detection and management of thyroid gland problems.

Locked Twins, Chin to Chin, Obstructing Labor

CHARLES H. McKENZIE, M.D., and
HENRY W. QUIST, JR., M.D.
Minneapolis, Minnesota

THE condition of chin-to-chin locking in twins, causing obstructed labor, is almost as rare as flying saucers. The quoted incidence of one such occurrence in 90,000 labors stems from the remark by Braun that he remembered only one such case in 90,000 deliveries in Vienna. In Minneapolis, in the past fifteen years there have been about 250,000 deliveries; the case to be presented appears to be the only such case, or one in 250,000 labors.

In reviewing the literature from 1912, only twenty-four cases of chin-to-chin locked twins have been found (Table I). Lawrence, in a report of a case in 1949 found fifteen previous reports. These have all been confirmed and eight more reports found to 1954. Four or five other references are presently unavailable. Less than thirty cases have been reported in the past forty years.

Treatment

The treatment of the locked heads depends on (1) the size of the fetuses and (2) the stage of labor. Beck,[24] DeLee,[25] and Titus[23] all state that if disengagement is not effected under deep anesthesia, decapitation of the first twin is indicated. However, Greenhill,[25] in the last edition notes "the condition would be ideal for laparotracheotomy as the opening in the uterus is immediately over the interlocked heads."

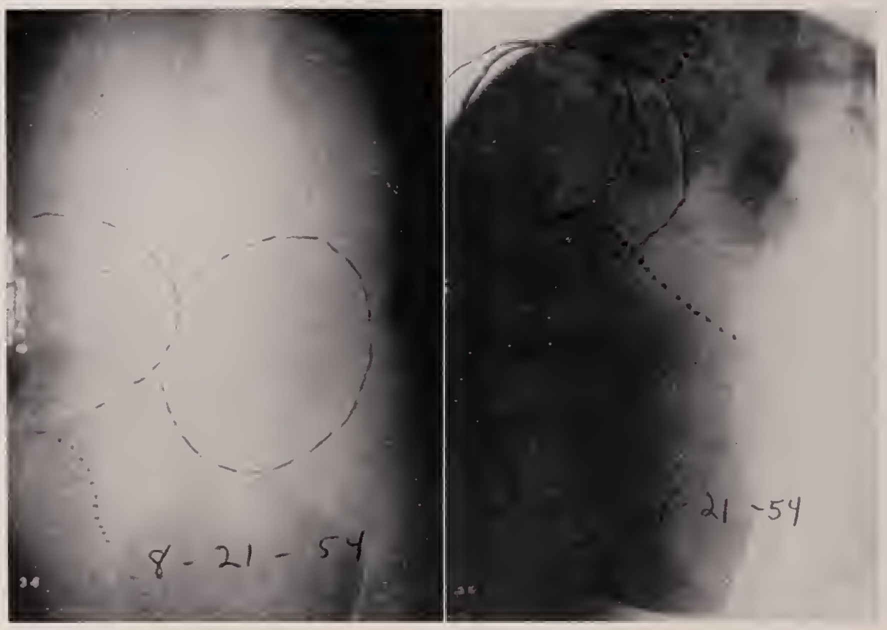

Fig. 1.

Kimball and Rand[18] ingeniously applied Piper forceps to the second head of small (4 pound) twins and delivered both alive. In the series presented eleven decapitations were done, disengagement was successful in three cases (six babies born alive), cesarean section was successful in two cases (four babies born alive, one neonatal death). The maternal mortality was 0 per cent but the fetal mortality (twenty-three stillborn, one neonatal death) was 50 per cent.

One can readily understand now the reason for the paucity of reports. We are therefore pleased to report the following case in which identical twin boys weighing a total of 14 pounds were delivered alive and well.

Case Report

Mrs. V. M., aged nineteen, gravida 1, had a due date of August 19, 1954. There was a family history of twins. She had a normal pregnancy, with a weight gain of 20 pounds. A flat plate of the abdomen on August 4 showed twins, one breech and one cephalic. There was a spontaneous onset of labor at 11:30 p.m. on August 19, 1954. The membranes ruptured spontaneously at 2:15 a.m. on August 20. She had mild contractions all day and was well sedated. A vaginal examination in evening of August 20 showed the cervix completely dilated, with breech at the spines. The patient was fatigued but not exhausted. In a telephone consultation, locked twins were discussed but considered improbable. The patient slept all night with no contractions.

TABLE II

Chin-to-chin locked twins	24
Gravida 1	17
Decapitation	11
Stillborn	23
Neonatal death	1
Uniovular	10
Mortality	
Maternal	0%
Fetal	50%

An x-ray at 8:00 a.m. on August 21 (thirty-two and one-half hours since the onset of labor, twelve hours in the second stage) showed chin-to-chin locked twins. Both fetal heart tones were heard.

Cesarean section was done from 11:10 a.m. to 12:15 p.m. on August 21 under spinal anesthesia (procaine 80 mg.). A transverse low incision was made in the uterus. The first twin was extracted by breech but the chin was unlocked manually with difficulty. The second twin, cephalic, was readily pushed through the incision. Both were males, the first weighing 6 pounds 15½ ounces, the second 7 pounds ½ ounce. There was a uniovular placenta, indicating identical twins. The patient had an uneventful afebrile recovery. The mother and babies were discharged on the eighth post-partum day.

ACUTE INFECTIOUS HEPATITIS: LABORATORY AIDS IN MANAGEMENT

GEORGE G. STILWELL, M.D.
Rochester, Minnesota

Acute infectious hepatitis, formerly known as catarrhal jaundice, has become an increasingly familiar problem to physicians during the past few years. In spite of the accelerated experience with this viral disease, many hiatuses exist in knowledge of its pathogenesis and epidemiology. The incidence of infectious hepatitis apparently is increasing at a rapid rate. In 1951, a total of 7,349 cases was reported in the United States. After the disease was added to the list of reportable conditions in 1952, the total jumped to 17,428 cases in that year. Approximately 50,000 cases were reported in 1954. Infectious hepatitis may occur in persons of any age and at any time of the year. Because its viral origin was recognized relatively recently, control measures have not yet evolved.

Two forms of viral hepatitis are encountered, namely, acute infectious hepatitis and serum hepatitis, the latter being transmitted by syringes, needles or blood contaminated with the virus. In the former variety, the virus appears in both blood and feces, whereas it is apparently present only in blood in serum hepatitis. The signs and symptoms in these two forms of the disease are similar, and routine laboratory tests cannot differentiate the two varieties. Most instances of acute infectious hepatitis probably occur as the result of spread from person to person, but relatively explosive outbreaks have appeared, suggesting transmission by contaminated food or water or both. Chronic carriers of the virus of infectious hepatitis possibly exist; it is suggested that perhaps 0.2 per cent of the general population carry the virus of serum hepatitis in their blood.

Diagnosis

One of the outstanding hallmarks of infectious hepatitis is the extreme fatigability, which may incapacitate the patient and which may be present for some time before jaundice occurs. The appearance of hepatomegaly and jaundice directs attention to the liver after the nonspecific prodromal signs and symptoms have been present for varying periods. Chills and fever frequently precede the jaundice by several days. Acute infectious hepatitis usually runs a self-limited and benign course of thirty to sixty days.

A most important factor in the management of infectious hepatitis is the recognition of impending hepatic insufficiency. For this purpose it is impossible to substitute laboratory data for the continued careful clinical observation of patients who have hepatic disease. The signs on which a prediction of impending hepatic coma can be based include an increase in abdominal distention, deepening of the jaundice, appearance of peripheral edema, onset of muscular twitchings and the occurrence of fresh spider angiomas. A peculiar odor of the breath, the so-called fetor hepaticus, may appear; this is a sweetish, not unpleasant odor probably caused by a tertiary amine and resembling the aroma of alpha methyl piperidine.

It is evident, then, that laboratory tests have a supplemental place in the original diagnosis of hepatitis and in the detection of impending hepatic insufficiency. Use of liver function tests does show the extent of hepatic damage but may not allow differentiation of the various types of hepatitis. The excretory function of the liver may be evaluated by such procedures as the measurement of total serum bilirubin, the amount of bilirubin in the urine, the degree of retention of sulfobromophthalein in the blood and the value for serum phosphatase. The functional state of the hepatic cells themselves may be gauged by the various flocculation and turbidity tests, such as cephalin-

---

From the Section of Publications, Mayo Clinic, Rochester, Minnesota.

This is the thirty-fifth in a series of editorial reports sponsored by the Minnesota Society of Clinical Pathologists and designed to foster closer relationships between laboratory physicians and their colleagues.

cholesterol flocculation, thymol turbidity and zinc sulfate turbidity, urinary urobilinogen, "prothrombin time," blood cholesterol, serum proteins and the synthesis of hippuric acid. Other tests that may be used include phenol turbidity, colloidal red, serum cholinesterase and measurement of gamma globulin.

If the results of most or all of these tests indicate hepatic dysfunction and if the patient has hepatomegaly and anorexia, the diagnosis probably is hepatitis. With negative cephalin-cholesterol flocculation and thymol turbidity and with normal or decreased urinary urobilinogen, biliary obstruction is more likely to be present. When the diagnosis remains doubtful despite thorough clinical and laboratory investigation, the physician is warranted in doing hepatic biopsy. The characteristic histopathologic features of viral hepatitis usually can be differentiated from the changes associated with extrahepatic obstructive jaundice.

As already indicated, laboratory procedures are of value as supplemental evidence of imminent hepatic insufficiency. Unfavorable changes in hepatic function may be indicated by (1) sudden or steady increase in the value of serum bilirubin, (2) sudden or steady decrease in urinary output, (3) sudden leukocytosis, which often is indicative of increased destruction of the hepatic parenchyma, (4) persistent reduction in the amount of serum albumin, (5) sudden or steady lengthening of the "prothrombin time" and (6) decrease in serum cholinesterase.

Laboratory Tests During Convalescence in Infectious Hepatitis

Probably the most important role of laboratory tests in infectious hepatitis is the aid they give in the management of the convalescent phase of the disease. Most tests of hepatic function are of little or no value during the acute stages of the illness, when the patient is jaundiced and obviously sick. However, such tests are of great value later in the course of the disease, when complaints are minimal or absent and abnormalities are not found on physical examination. These tests should be performed at regular intervals during convalescence, so that significant changes, either progressive or regressive in nature, will become readily apparent.

Analysis of the large battery of tests of hepatic function that are available indicate that three procedures are of prime importance in such a program. These are the sulfobromophthalein test, the thymol turbidity test and measurement of total serum bilirubin. Use of these three tests is adequate to demonstrate persistent or recurrent hepatic dysfunction throughout the period of convalescence in infectious hepatitis. The cephalin-cholesterol flocculation procedure is also of value according to many workers, although others state that it is insensitive in later phases of the disease and thus may be misleading.

Retention of sulfobromophthalein is undoubtedly the most sensitive indicator of hepatic dysfunction after jaundice has disappeared. As many as 35 per cent of patients still have definitely abnormal retention of this dye as long as seven weeks after jaundice has gone. At the same time, the thymol turbidity test may show positive results in about 25 per cent of convalescents, as does the zinc sulfate turbidity test, whereas the results of practically all other tests of hepatic function may be normal except for a few scattered positive reactions. The amount of total serum bilirubin also should be determined weekly during convalescence, even though the sulfobromophthalein test is a more sensitive indicator of a relapse.

By periodic use of these tests, the physician can minimize the dangers of allowing the patient to resume full activity too early and can detect impending relapse at the earliest possible moment. Conversely, such studies will avoid unnecessary prolongation of rest in bed and an undue delay in the return to full activity, factors that may be of particular importance to military personnel.

Because of the aforementioned self-limited nature and the usual benignancy of infectious hepatitis, conservative management is used almost universally. The two main factors in this regimen have been a high-protein, high-carbohydrate diet and adequate rest in bed. Some recent surveys tend to minimize the importance of a strict diet and undue restriction of activities.

Investigators associated with the Armed Forces have recommended the following program of management of infectious hepatitis, governed by the results of laboratory tests.

1. The patient is confined in the hospital or at home and stays in bed if he feels sick. He may get up if he feels able, except that he must rest for 1 hour after each meal.

2. The total serum bilirubin is determined regularly until it is less than 1.5 mg. per 100 ml.

Current Concepts

THE VALUE OF PROLONGED ANTICOAGULANT THERAPY

JOSEPH F. BORG, M.D.
Saint Paul, Minnesota

Since the contributions of Wright[1] and coworkers and Nichol and Borg[2] concerning prolonged anticoagulant therapy, many favorable reports have appeared. Such treatment has received increasing acceptance in many thromboembolic conditions.

1. *Recurrent embolization associated with rheumatic heart disease and auricular fibrillation.* This complication, especially when associated with cardiomegaly and stubborn decompensation, occurs much less frequently when patients are kept on prolonged anticoagulant therapy. These patients are especially susceptible to such recurrences, and treatment should be continued indefinitely. With a relatively small heart and easily controlled compensation, some investigators suggest that therapy may be stopped after about six months.

2. *Recurrent pulmonary infarction, thrombotic or embolic.* This condition, frequently of unknown cause, may be a serious condition leading to pulmonary suppuration and its dangerous complications. It may simulate pneumonia and should always be suspected in a patient with heart disease when an unexplained break in compensation appears. Often unrecognized, it occurs so often in congestive heart failure that the use of anticoagulants in this group of patients is widely advised. Treatment should be discontinued only when all possible causes seem likely to be under control.

3. *Multiple arterial occlusions, thrombotic or embolic, occurring anywhere in the body regardless of cause.* These may occur especially in angiitis, arteriosclerosis, or heart disease with associated mural thrombi, and their recurrence lead to crippling conditions. With our present knowledge, it is probably better to exclude emboli from bacterial endocarditis from this category. Treatment should be continued until the cause is determined to be probably inactive.

4. *Recurrent thrombophlebitis, especially when occurring at rather short intervals of time.* These conditions occur usually in the lower extremities and may be deep or superficial. If treatment seems ineffective, consideration of the possibility of malignancy, especially obscure visceral carcinoma, must not be overlooked. Therapy should be continued several months after the cause is apparently under control.

5. *Myocardial infarction.* The frequency of recurrence of this condition, especially in the first two years after an initial attack, has led to an increasing acceptance of prophylactic long-term anticoagulant therapy. Recurrences and thromboembolic complications appear to occur much less frequently in the treated groups. These observations must be confirmed by others with much larger series of patients before it can be regarded as conclusive. Personal experience with the use of ambulatory anticoagulant therapy over the past eight years has prompted continuance of this therapy and its recommendation to others. Treatment should be maintained at least two years, probably indefinitely.

6. *Impending myocardial infarction.* Prevention of an initial myocardial infarction is considered by many to be sufficiently likely in a certain group of patients to justify anticoagulant therapy to be continued over a long period. This group includes (1) those patients who with no history of previous cardiac pain begin a series of spells of moderate cardiac distress without significant provocation and (2) a group of angina pectoris patients who abruptly begin to have increased frequency and severity of attacks. The recognition of these groups supplies the only hope available for forecasting an infarction, and it is my opinion, among others, that such patients be immediately started on anticoagulant therapy and treated as a myocardial infarction until the course makes sufficiently clear that myocardial necrosis has not occurred. Prolonged therapy is as justifiable in these cases as in those who have had a demonstrable infarction.

Details of management of therapy, selection of anticoagulants, contraindication and discussion of hemorrhagic complications must be sought elsewhere.[1,3,4] The risk in well-controlled anti-

VIVE LA DIFFERENCE

A December issue of *Life* magazine tells us about the pre-Presidential nomination activities of Adlai Stevenson, and about the effectiveness of the Democratic-Farmer-Labor political party in stirring up political interest; for example, in Duluth even the hospitals were canvassed—except, of course, the hospital that was the home of the rich Republicans. We understand that this exception to an otherwise universal canvass was made because of fund- or interest-raising expediency. And precisely there lies a difference that deserves iteration and reiteration, emphasis and re-emphasis.

After years of observation of the medical scene and the hospitals in Duluth, we know that to the physicians of Duluth, all of the hospitals house individual patients. Some of these patients are Republicans, some are DFL, some don't care, and some might even be mugwumps—but they are all individuals and patients. No physician, so far as we can learn, has ever avoided any hospital because it contained Republicans, DFL's, negroes, whites, Jews, Christians, or whatever. Mark this difference then: the *individual* is the focus for the attention of our independent practitioner of medicine, but the politician and political machine act on the basis of the political convictions or leanings of a *group*. No need to picture for you what might result when a patient with political leanings at variance with those of the party in power would seek medical care from a politically administered system of medical practice.

Preventive medicine may work on a *group* basis: military medicine may work on a *group* basis: but the medical care of one person must be personal and *individual*ized. We say, long live the difference, and may we find forceful enough means to convince even our least sincere politicians of its profound reality.

H.G.M.

ORAL COMMUNICATION

Have you ever been surprised by a patient's explanation of what he thought you meant by your oral instructions? Undoubtedly, you knew exactly what you wanted him to do and you may have used words of one syllable. But somehow he just did not get the idea.

Who is at fault in this kind of communication failure? Is it the patient? Or is it you, the doctor? The human reaction is that it must be the patient. "How can anyone be so stupid as not to undestand me?" Unfortunately, such a diagnosis does not help us prevent future errors in communication.

The key to a good deal of our communication failure is in the phrase, "He didn't get the idea." How does one get an idea? Most of us seem to have the notion that an idea is something exact that can be communicated from one person to another in the same way water is transmitted through a pipe. As beautifully simple and desirable as this notion is, it is psychologically unsound. Words are merely symbols for things within our own experience. The idea you, the doctor, have is colored by all of your years of medical schooling and experience. The idea the patient gets is colored by his strange modern world of pseudoscientific advertising, a world in which science and magic are one. Radio and TV tell him about new "scientific" discoveries which would put any witch doctor to shame. The patient "knows" about "immediate relief from pains of arthritis and neuritis." Is it any wonder that the patient comes to you expecting some pretty high power mumbo jumbo?

Sensing the difficulty of communicating with a patient, many doctors have adopted the policy of telling the patient as little as possible. Whatever they do tell him is then phrased in such technical language that he cannot understand anyway. Unfortunately, this approach only furthers the patient's notion that medicine and magic are brothers. The patient gives up trying to understand his ailment and instead puts himself into the complete trust of the doctor just as his primitive brother used to do with the tribal medicine man.

In order to improve oral communication with the patient, the doctor must strive toward a two-way flow of communication. Merely asking the patient whether he understands your instructions is not enough. Because of pure ignorance, the patient will answer, "Yes." This tells the doctor nothing as to the degree of understanding which has taken place. A better approach is to provide the patient with a few of the facts phrased in non-technical language and then lead the patient into a discussion of his case.

Although better oral communication with the patient will demand more time from the doctor, the time spent may be a good investment. The possibility of the patient's taking better care of himself, the dispelling of the note of magic in medicine, and the development of a more sympathetic attitude toward the medical profession are only a few of the possible outcomes of better oral communication.

Department of Rhetoric
University of Minnesota

PSYCHOSOMATIC MEDICINE

Psychosomatic medicine, in the strict sense of the word, refers to a specific group of stress disturbances manifested by autonomic nervous system or endocrine dysfunction, and apparently caused by a combination of psychological and somatic factors. Psychosomatic medicine is not synonymous with psychiatry; it does not include all illnesses with psychological and somatic factors in either causes, symptoms, results or sequelae (or it would be synonymous with the whole field of medicine); and it is not properly a definition of conditions, such as suicide, with emotional causes and somatic consequences.

The primary concern with psychological factors expressed by most investigators in psychosomatic medicine results mainly from the greater promise these factors give of developing a more effective treatment approach, and not because the somatic factors are less important. Earlier expectations that a specific personality pattern could be found for each psychosomatic illness have not materialized; current investigations suggest that patients with psychosomatic disturbances of any kind rely primarily on the mechanisms of unconscious repression and reaction formation to conceal from themselves and others residual dependent strivings and aggressive impulses. As children, they apparently failed for various reasons to satisfy the strivings or to find appropriate outlets for the impulses; at the same time they developed enough personality strength to keep these unresolved problems from obvious interference with their adjustment to the environment. Consequently, they seldom appear "neurotic," to themselves or to others, and often resist exploration of their personality problems.

However, these disturbances are for the most part progressive and disabling, and the psychological factors do not respond well unless treated early. Therefore, the physician should search for contributory psychological as well as somatic components at the time of the initial diagnosis of psychosomatic illnesses such as peptic ulcer, ulcerative colitis, essential hypertension, thyrotoxicosis, glaucoma, migraine, rheumatoid arthritis, and certain types of bronchial asthma and eczema. An early assessment of the relative significance and treatability of each factor in each individual case expedites the planning of treatment. Although absolute proof is lacking, there is strong evidence that treatment of psychological factors reduces the frequency and intensity of exacerbations, and delays the development of irreversible changes in many of these conditions.

C. Knight Aldrich, M.D.

PRESENT TREATMENT OF PULMONARY EMPHYSEMA

Despite the unknown etiology of chronic pulmonary emphysema, significant advances in therapy have been made in the past decade based on the alterations in physio-pathology in this disease. With no single specific "cure" available, the complexity of proper management requires a knowledge of cardio-respiratory physiology, clinical bacteriology, allergy, and the pharmacology of bronchodilator and corticosteroid agents. More recently, the psychotherapist and thoracic surgeon have become a part of the therapeutic "team."

Improvement in the ventilatory function of the lungs results from the use of measures designed to (1) relieve bronchospasm, (2) aid in the elimination of retained secretions, (3) control sino-bronchopulmonary infection, (4) correct hypoxia and disturbances in acid-base balance and (5) reduce the state of hyperinflation of the chest and promote diaphragmatic breathing.

The inhalation of sympathomimetic aerosols such as racemic epinephrine (Vaponefrin) or isopropyl arterenol (Isuprel) are of great value in the relaxation of bronchospasm. Deliberate coughing following aerosol inhalation frequently aids in the expectoration of retained mucus. Oral administration of aminophyllin and ephedrine may be useful in long-term management. With more severe bronchospasm, the rectal administration of aminophyllin dissolved in water has been more effective. The use of the corticosteroids and prednisone may be life-saving in the presence of intractable bronchospasm. These are especially useful when persistent, severe obstructive dyspnea follows an upper respiratory infection or exposure to a specific allergen such as pollen.

The use of saturated solutions of potassium iodide, syrup of ipecac and intermittent courses of Fowler's solution may aid the patient in his ability to expectorate viscid sputa. Lowering of the surface tension as well as humidification is obtained with detergent aerosols such as Alevaire (0.125 per cent oxyethylated tertiary octylphenol formaldehyde polymer). In the presence of tenacious purulent secretions, the use of a proteolytic enzyme aerosol such as Tryptar (crystallin trypsin) or Pancreatic Dornase (pancreatic desoxyribonuclease) has been used. There has been some disagreement as to their effectiveness and local irritation consisting of pharyngitis and glossitis has been encountered with Tryptar aerosol when inhaled for five days or more. The most useful of the mechanical methods of accomplishing bronchial drainage in co-operative patients is Exsufflation with Negative Pressure (EWNP). The high expiratory flow rate achieved with this device is often responsible for aiding in the elimination of mucopurulent plugs which the patient cannot expectorate with his natural cough. Intermittent pressure breathing devices, such as the Bennett, M.S.A., Emerson and Halliburton, while helpful in conjunction with aerosol therapy especially when the alveolar ventilation is inadequate, do not provide adequate changes in pressure gradient necessary to simulate cough.

Aerosol therapy with penicillin and/or other antibiotics is indicated in the treatment of a coexisting sinusitis, bronchitis or bronchiectasis. The long-term arrest of chronic bacterial infection plays an important role in the management of the patient with pulmonary emphysema. The broad spectrum antibiotics, administered orally for periods of six to ten days, are especially useful in acute suppurative infections of the sinuses and bronchi that frequently follow a "common cold." Prolonged use of the broad spectrum antibiotics may be hazardous since a change in bacteriologic flora with superinfection or the emergence of a resistant organism has been encountered.

The relief of hypoxia by oxygen therapy is often necessary especially during an acute exacerbation of obstructive dyspnea. The sudden administration of high concentrations of oxygen may produce hypoventilation, retention of carbon dioxide, and respiratory acidosis accompanied by disturbances in the state of consciousness, coma and death. Oxygen therapy should be begun with low concentrations provided by a 1 or 2 liter flow per minute, administered with a double-bent nasal catheter. The oxygen concentration may be raised gradually, a liter per minute each day, until a level of 6 liters per minute is reached; a gradual reduction, usually requiring five to seven days, should be employed at the termination of therapy. The treatment of respiratory acidosis requires the use of devices which increase the minute ventilation, such as the tank respirator, IPPB, or the Exsufflator with Negative Pressure in addition to steroid and bronchodilator therapy. The use of a carbonic anhydrase inhibitor (Diamox) has been of value in a few instances.

Overinflation of the lungs is reduced by manual compression of the lower ribs and upper abdomen after the inhalation of bronchodilator aerosols. Together with pursed lip-breathing during the expiratory phase of the respiratory cycle, more complete emptying of the alveoli is possible since these maneuvers tend to maintain a wider bronchial lumen and aid in the expulsion of retained secretions. The enhancement of diaphragmatic breathing by active and passive breathing exercises improves ventilatory efficiency and is, perhaps, the most valuable measure in the long-term management of patients with pulmonary emphysema. Training is facilitated by the head-down position or by placing a 10-pound weight over the lower abdomen. The patient is encouraged to inspire by diaphragmatic contraction with expiration aided by the increase in intra-abdominal pressure provided by the weight. These exercises are continued as a daily routine, and when properly learned, appreciable diaphragmatic movement occurs in the upright position. The use of an abdominal emphysema belt aids and encourages diaphragmatic breathing in the trained ambulatory patient. Pneumoperitoneum has been used infrequently and appears indicated only in a small percentage of asthenic patients in whom elevation of the diaphragm could not be achieved by exercise and a properly applied belt. The dangers of aeroembolism, infection or hemorrhage have limited its applicability to the physician with specialized training.

Columbia University

DIVORCE AND FAMILY RELATIONSHIPS

Preparing and presenting petitions for divorce is one of the responsibilities of the Legal Aid Department of Family Service. No legal aid service is provided for any family whose income would permit the use of a private attorney. Clients come upon referral from the County Welfare Board, other social agencies, lawyers, former clients, and the citizenry in general who know of the service.

Due to the pressure of work in the attorney's office, there is a long delay between the request for a divorce petition and the drawing up of the papers. This interim period gives the caseworker who takes the application an opportunity to help both spouses try to find a way of living together which will give some satisfactions to the whole family.

Some homes have been broken long before the legal process occurs. Fathers or mothers may have left the community months or years ago. No address is known by the remaining partner nor by the paternal family or friends of the missing parent. Families could bear the physical separation if there were evidences of affection given them such as birthday cards, Christmas greetings, valentines, or a money gift now and then. But when families have experienced no evidence of love, let alone evidence of a feeling of responsibility from an absent parent, the actual obtaining of a divorce merely confirms a break already made.

Each parent bears a responsibility for making a happy home. Perhaps the marriage got off to a poor start because neither had a happy family as a pattern for future living. Perhaps the husband and wife have difficulty in making a good life because of a great difference in their own backgrounds. Sometimes the needs of one partner are so great they can scarcely be met by the other, no matter how much effort is put into the marriage. Helping families find a balance, satisfactory to them, may take a long time even though each partner tries.

Broken homes bring some problems to their members which might not have been taken into consideration when divorce was sought as a solution to other problems. Because children are usually given to the custody of the mother, she finds herself trying to be both father and mother. Her confidence has been shaken as a wife, yet, in that unenviable state of mind, she must meet emotional and maybe financial needs formerly shared by her husband, at least theoretically. Children are quick to take advantage of indecision, and the mother, unable to set limits for behavior, finds herself with less and less control of her children to their detriment. The father, too, has new problems. He may visit his family, but that is an artificial manner of association with his children, so unsatisfactory that he gradually drifts away, and becomes only the provider of a "court order" for which he gets little thanks or appreciation from his children, and only a feeling of frustration for himself.

Loneliness is hard to meet, so each may seek a new marriage. Second marriages of either partner can produce the same or different problems. There is the adjustment to the new parent, followed perhaps by adjustments to other children. There are the financial problems due to two families and loyalties to each.

While divorce is often a necessary result of long-continued unhappiness, it should be approached slowly and carefully, and only after counseling. Marriage counseling is available at Family Service for everyone who lives in the area supported by the Community Chest.

TRAVELERS CHECKS AND LETTERS OF CREDIT

An item often neglected in planning summer vacations is the protection of travel funds. Nothing can spoil a vacation trip more completely than lost or stolen money.

Protecting your travel funds is really a simple matter. Just convert them into safe and convenient Travelers Checks at your bank. Travelers Checks can almost be called an international currency, because they're accepted everywhere and can be spent like cash anywhere with just your signature for identification. You sign them when you buy them, and countersign them when you cash them. It's the likeness of the two signatures that makes the checks cashable. For convenience, they come in denominations of $10, $20, $50 or $100, and they cost only 75 cents per $100 worth.

Travelers Letters of Credit are another bank service which protects funds. This service is of particular value to persons traveling abroad who wish to carry additional funds for emergency purposes, or for expensive purchases. It should be used to augment your Travelers Checks, not take the place of them. A Travelers Credit can be applied for at your bank. It is your bank's letter of instruction (in special form) to correspondent banks all over the world to pay you money as you request it, but not to exceed the amount stipulated in the Credit. Letters of Credit are usually not issued for amounts less than $1,000. At the time of issuance, you will be given a list of banks, and their locations, where you will be able to draw money under the credit. Payments will be made by these banks in the United States or foreign countries upon presentation of the Letter of Credit and your signature.

Because of the low cost and wide acceptance of Travelers Checks, Travelers Letters of Credit are not used as much as they once were. The main objections are the limitations on places and banks where cashable, and the fact that if the credit is lost or stolen it will cost the purchaser approximately $150 to have a stop payment placed against it. Travelers Checks, however, are safe, convenient, and can be spent anywhere at practically anytime. And if they are lost or stolen, your money will be promptly refunded at no cost. Don't spoil your vacation. Protect your travel funds by using Travelers Checks.

NEW FIELDS AND RESPONSIBILITIES IN TUBERCULOSIS RESEARCH

At no time in history have so many avenues of approach been open to the investigator who would learn the secrets of tuberculosis. It must be admitted that so far the acquisition of basic dependable information has been difficult and slow, but there is now great hope that new advances, many of immediate practical importance, will soon be realized if current programs are expanded. A few examples can be cited.

Although it has been known for more than fifty years that a limited but definite immunity to tuberculosis can be induced by the use of dead or attenuated tubercle bacilli, the nature and location of that immunity and the specific antigen or antigens involved have been extremely elusive. The refinements of protein chemistry, tissue culture and other laboratory techniques now seem to be leading to some understanding of the mechanisms involved and perhaps to improved vaccines and specific tests for clinical tuberculous activity.

Dr. Emil Bogen in California has demonstrated the existence of several bacteriophage strains capable of lysing tubercle bacilli. From work in progess, it now appears that lysogenic tubercle bacilli also exist. It can be predicted confidently that cultivation of this new field would unearth a wealth of new knowledge.

The successes of modern drug and surgical treatment have hinted at spectacular developments and have received wide publicity, but the public is not sufficiently aware of the shortcomings of the therapeutic tools currently available. There are many failures in treatment. In selected cases, the results are often miraculous, but in many others the fatal outcome is merely delayed and relapses are frequent. Only three effective drugs are in general use, and none is completely bactericidal. All of them are so slow in their action they must be given for months and even years. New drugs and new combinations of drugs can be discovered and developed only through research.

We have a great need for the immediate expansion of tuberculosis studies. The catalyst is money. The Public Health Service, the Veterans Administration, the tuberculosis associations and other official and voluntary agencies are doing what they can but it is not enough. Surely, this nation which prides itself on doing the difficult immediately, and the impossible if given a little time, will not accept a stalemate in the battle against a lowly, single celled, non-motile plant which continues to sicken enough citizens every year to maintain a constant total of 400,000 active cases.*

Floyd M. Feldmann, M.D.

THE NURSING TEAM

The nursing team represents an attempt to provide high quality of nursing service at a time when the number of graduate and student professional nurses cannot keep pace with demand. Although their number is greater than at any other time in our nation's history, except during the Nurse Cadet Corps period, it has become necessary to utilize other personnel able to provide supplementary service.

---

*Estimate by Public Health Service and National Tuberculosis Association.

Practical nurses, taught to contribute the more non-technical and non-judgmental aspects of nursing under the supervision of a professional nurse or physician are integrated into the nursing staff as members of the nursing team. Nurses' aids, trained on the job, are also members of the team in hospitals where they are employed. The team leader, sometimes a registered nurse and sometimes an able professional student, with her team is responsible for the care of the group of patients assigned to her by the head nurse. The leader will decide the best way to use the knowledge and skills of the individual team members to provide the highest possible quality of nursing for the team's group of patients, and she will supervise and teach the members of her team as they carry out their assigned duties.

To be effective, there are some very essential principles to be followed.

1. The entire hospital staff must be carefully oriented to the concept of team nursing and its methodology.

2. Professional nurse team-leadership must be adequate to provide indicated supervision of non-professional nurse members of the team.

3. All team members must believe in the philosophy of team work and must understand individual assignments thoroughly.

4. The team leader is administratively responsible for the patients in her group and therefore medical staff members should communicate with her in regard to their patients.

The personnel constituting a nursing team varies within the same hospital and from one hospital to another. In addition to the leader, the team may include other professional nurses—graduate and student, practical nurses—graduate and student, nurses' aids, and orderlies. On the other hand, any one or more of these may be absent.

If members of the medical staff in a hospital find nursing service being provided by nurse teams and are a bit confused by it, they will find members of the nursing staff most eager to discuss the concept with them either individually or at a medical staff meeting.

LOCKED TWINS, CHIN TO CHIN, OBSTRUCTING LABOR

(Continued from Page 36)

Comment

An x-ray picture of all twin pregnancies for diagnosis of fetal positions early in labor is desirable; if the first fetus presents by breech or footling, x-ray is essential.

Discussion

Dr. Roger Countryman, St. Paul, presented a report of chin-to-chin locked twins. A short very active labor brought the breech of the first baby through the introitus before unlocking of the heads was possible. Decapitation became necessary for delivery of the first twin. The second twin was delivered normally and survived.

Dr. Leonard A. Lang, Minneapolis, presented a report of chin-to-chin locked twins. When the breech of the first did not descend readily, x-ray was taken, revealing the locked chins. He was successful in pushing up the breech of the first twin, unlocking them, and then was able to deliver both twins alive.

R. H. WILSON, M.D.

President, Minnesota State Medical Association

President's Letter

To Members of the Minnesota State Medical Association:

This is my first message to you as President of your Association, and I want to take this opportunity, first, to wish you all a very happy and prosperous New Year. I want to take this opportunity, also, to express my deep appreciation of the honor you have conferred on me. I hope I may prove worthy of it.

I would also like to be the worthy representative, especially, of that great group of men who practice good medicine outside the big cities of the state, some of them hundreds of miles from the great centers of teaching and research. These are the men who man the battle stations of medicine, and I hope that I can say, when January rolls around again next year, that I have helped a little to protect their freedom as doctors and to keep their standards high.

To do so, I shall certainly need the help of the Council and officers of the State Association for their invaluable wisdom and experience. I shall also need the help of county medical society officials all over the state. They are busy men, I know, and they have little time for anything outside their own programs and problems. But I am going to count heavily on them, too, because the success or failure of our work as an organization depends largely on how well we meet their needs.

It is certainly true that times are good as we begin this year of 1956. Furthermore, our patients have confidence in us, as many recent surveys have shown. But the millenium in medicine has not arrived, for all that.

There are still threats of regimentation on the horizon, though they are taking on new forms. Welfare costs are rising, and physicians unfairly get the brunt of the blame for that. Some Minnesota towns are still without doctors, and more doctors and hospitals are needed in many areas of the state. These seem to be perennial problems. There are others, and our state organization must be geared to meet them all.

As chairman of a committee which has dealt for many years with welfare and relief, I have seen how the close and conscientious co-operation of medical organization with the official agencies can operate to solve many of the major welfare problems in this state. I am confident that the same kind of co-operation in other fields will go a long way toward keeping medicine free and standards of practice high in Minnesota.

I follow a long line of distinguished and dedicated men who have devoted themselves to that end. I cannot do better than to follow in the spirit in which they have led.

R. H. Wilson

George Earl, M.D., Chairman

SOCIAL SECURITY—BIG ISSUE IN 1956

Every physician who is conscious of his duties as a citizen should now be taking an active interest in a timely issue which the American Medical Association considers of great importance—not only to the medical profession but to all of the American people.

That issue is HR 7225, a bill passed by the United States House of Representatives last summer near the end of the Congressional session. This bill, known as the Social Security Amendments of 1955, was first rushed through the House Ways and Means Committee without public hearings. Then it was passed in the House, by a vote of 372 to 31, under a suspension of the rules which barred amendments and limited debate to forty minutes. The Senate Finance Committee, however, refused to take hasty action on a bill of such major importance. After hearing the many serious questions raised by Mrs. Hobby, then Secretary of the Department of Health, Education and Welfare, the Committee decided to hold extensive public hearings during the second session of the 84th Congress.

Just what is this legislation that appears to be so politically attractive to individuals with an eye on the 1956 elections? Why was the House majority leadership so determined to avoid open hearings and normal debate? Let's take a brief look at the main provisions of the bill.

This is the legislation which would lower the Social Security retirement age for women from sixty-five to sixty-two; extend monthly benefits for permanently and totally disabled children beyond the age of eighteen; expand compulsory social security coverage to all self-employed professional groups except physicians, and raise social security taxes over and above the increases already scheduled for the next twenty years. Those provisions alone demand careful study of their effects on the philosophy, scope and financial stability of our social security system.

Serious Implications in Bill

The most controversial section of the bill, however, is the one which would make permanently and totally disabled persons eligible to receive their social security retirement benefits at age fifty instead of sixty-five. It is this section which is of particular concern to the medical professsion. It is of far greater concern than the question of voluntary or compulsory coverage of physicians under the Social Security system. That is a separate issue which we are not discussing in this editorial. The plan for a national system of permanent and total disability benefits has far more serious implications for medicine and the nation.

It raises questions such as these: Is there any real need for a federal program? What are the facts on permanent and total disability? Won't this duplicate or overlap existing programs of assistance and rehabilitation? What effect will cash handouts have on a patient's incentive to be rehabilitated? Won't this extend federal control over physicians? —and, finally—How will this affect the future of medical practice? Will this lead, step by step, to the lowering and eventual elimination of the age-fifty eligibility requirement; then, cash benefits for the dependents of those who are permanently and totally disabled; then, a temporary disability benefits program; then, cash benefits or direct government payments for hospital or medical costs, and then, ultimately, a full-fledged system of government health insurance?

These are but a few of the many grave questions which already have been raised concerning this legislation. As physicians, we must be concerned over the medical aspects of the problem. As citizens, we also must be concerned over the trends and implications in the never-ending expansion of our social security system. The minority report of the House Ways and Means Committee expressed it this way:

> "We do not believe that our committee has discharged its obligation to either the Congress or to the American people by its brief and closed-door consideration of this vital legislation. We have sought to point out the grave social and economic implications of the bill. We have dwelt at some length with the staggering ultimate costs of this developing program, because we do not believe that either the Congress or the public has any conception of its magnitude."

Our social security system now has reached the point where any further changes may have a profound influence on the nation's economic, social and political future. The time has come to face up to the question of just what social security should accomplish and just where it should stop. The Association strongly *urges* that the social security issue be taken out of the arena of vote-catching politics; that there be an objective, thorough study of social security in all its present and future aspects, and that the facts and realities emerging from such a study be used as the basis for a sound national decision on this vital issue. It especially protests precipitate action on the complex question of disability without thorough investigation of alternative mechanisms.

In our opinion, that is a reasonable, responsible policy that deserves the moral and intellectual support of every physician.

NORTH CENTRAL MEDICAL CONFERENCE MEETS IN SAINT PAUL

The North Central Medical Conference had its usual vigorous, well-attended meeting this year on November 20 in Saint Paul. Lay-sponsored Medical Plans and the Relationship Between Physicians and Hospitals were reported on and discussed.

Medicine has been progressing in giant steps during the past few years. The health of the citizens of this country has never been so good or received such wise and competent care. Yet doctors, as guardians of the public health, must be more alert than ever to protect the quality of this care. Panaceas that offer solutions to health problems are often deceptive. One of the most important functions of the North Central Medical Conference was to raise pertinent questions about some of the current cure-all plans.

Doctor Earl Notes Current Trends

Dr. George Earl keynoted the meeting with his presidential address, a general discussion of trends in health care today.

Some of the most important of these trends are:

1. More individual voluntary prepayment health insurance and/or services.
2. More group arrangements for such services.
3. More unions or co-operatives handling health problems.
4. More provisions for large veterans' installations and medical care, and for tax-supported hospitals of all types.
5. More public health nursing services and activities.
6. More lay-controlled groups, outside of unions and co-operatives, sponsoring health care plans and services.
7. More political activities and interest, with increasing legislative enactment in the health field.
8. A general increase in the public's health consciousness and what can be done to make the nation's health better.

Must Take Stand on Legislation

Dr. Earl said:

> "Politics have become bound up with matters of health care and medicine has found itself in a position where it must make political decisions. When our lawmakers move toward legislation affecting medicine, we as a profession must consider it carefully in the light of all previous experience, and take a definite stand on its merits."

Lay-sponsored Medical Plans

E. L. Bernhart, M.D., president of the State Medical Society of Wisconsin; J. E. Kelsey, M.D., Des Moines, Iowa; and A. O. Swenson, M.D., president of the Minnesota State Medical Association, spoke on lay-sponsored medical plans.

Dr. Bernhart favored expansion of Blue Shield and other prepayment plans to greater numbers of people. But the cost of these programs must be kept within the budget of industry and within the reach of the individual members, he said.

> "More than 150 million people can be enrolled under the voluntary system of health insurance if we have the whole-hearted support of the medical profession," he said, "and only with this attitude will we avoid the destruction of the private practice of medicine. Only with this attitude will we preserve the gains we have made. The legislative hoppers of states and the United States contain many dormant proposals which, in the light of today's economy, would put Wagner, Murray, and Dingell to shame as social planners . . ."

Dr. Bernhart added:

> "Industry pays the bill for prepaid medical insurance. Labor seeks to extend the benefits of prepayment. The medical profession can and will render those services to the mutual advantage of all and will continue to do so on a voluntary basis when they look the facts in the face."

Doctor Kelsey Talks on Kaiser Foundation

There are more than 525 physicians participating in the health plan of the Kaiser Foundation and facilities, including eleven hospitals and many clinics with a total bed capacity of about 2,000. To call this a medical empire is no exaggeration.

According to Dr. Kelsey, the plan is successful; it is popular; and many of the facilities are outstanding. The cost to the patient is roughly equivalent to that of other voluntary insurance plans in California. Why, then, is there opposition to the plan in the medical profession?

Organized medicine's opposition has been to the "closed panel" aspect of the group. To counteract such plans, Dr. Kelsey recommends, ". . . the establishment of a method of comprehensive coverage for disease, which is prepaid, which can be offered to all income groups, comprehensive in scope, and which permits a free patient-doctor relationship and a free exchange of ideas between all physicians. Kaiser and other closed panel plans will continue to grow until this challenge is met."

Union Medical Care Plans Expanding

Dr. A. O. Swenson described the history of union medical care plans which gained impetus during World War II when wage increases were practically halted. Health and welfare plans became of prime importance in union-management negotiations.

Those advocating co-operative systems of medical care are insistent on lay control, comprehensive care and preventive medicine associated with group practice. The insurance principle is ignored.

Dr. Swenson suggested that a definite set of policies be developed for medicine to follow in consultation about these plans. Medical care problems relating to sanitation, safety and preventive medicine in industrial plants should be paid for by management. Medicine should take the leadership in the area of fringe benefits concerning health and in developing medical care plans that are adequate for both preventive and curative medicine. The development of lay-sponsored clinics has not been satisfactory due to the lack of personalized service, loss of efficiency and the removal of competitive influence.

Physician-Hospital Relationships

F. C. Coleman, M.D., Des Moines, Iowa; A. J. Offerman, M.D., Omaha, Nebraska; and D. H. Breit, M.D., Sioux Falls, S. D., covered the drastic change in physician-hospital relationships in the past quarter century. The hospital originally was built and operated by the doctor to care for his ill patients more effectively. Now the function of the hospitals has expanded to include many more services and lay personnel has taken over the responsibilities of administration.

Among the reasons for this shift is the fact that there are many more diagnostic procedures, some utilizing radiology and pathology, and the most convenient place for this equipment is the hospital. Gradually, radiologists and pathologists have "set up practice" in hospitals, sometimes being paid directly by the hospital. This has led to the adoption, among some hospital administrators, of the premise that the next step is for the hospitals to employ physicians generally as salaried personnel. The implications are serious.

Dr. Coleman discussed a lawsuit of the Iowa Hospital Association and thirty-four member hospitals against the Attorney General, the Iowa State Board of Medical Examiners, and the Iowa Association of Pathologists. Since the Conference, this suit has been settled against the plaintiff. It was the conclusion of the Court that work done by the pathologist and radiologist constitutes the practice of medicine. Hospitals should not sell the services of these specialists. This decision will have an important influence on hospital-physician relationships.

Good relations exist between hospitals and medical groups in Nebraska. The foundation of this satisfactory relationship, according to Dr. A. J. Offerman, was the exclusion of benefits for medical services in the Blue Cross contract.

In his discussion, Dr. Breit emphasized that a sharp distinction should be maintained between hospital and medical services. Medical services should be under the unhampered direction of physicians and the energies of hospital administrations and personnel could be directed toward the original purpose of caring for the sick.

At this moment, it is exceedingly important that the decrease in the number of new cases of clinical tuberculosis evolving and the precipitous decline in mortality are not interpreted as the approach of immediate ultimate victory over tuberculosis. Such an interpretation could play into the hands of the tubercle bacillus, which could soon again become as widespread and destructive as it was in this country fifty years ago. The phenomenal success in reducing morbidity and mortality represents a battle less than half won against the tubercle bacillus.—Editorial, J. Arthur Myers, M.D., *Journal-Lancet,* April, 1955.

The Dean's Page

WANTED: MORE APPLICANTS FOR MEDICAL SCHOOL

Surprisingly, for most physicians, every medical school in the United States might well hang out such a sign on its front door . This does not mean that medical schools do not have sufficient number of applicants to fill their classes. It does mean that the number of well-qualified applicants has dropped to a point that Admissions Committees have become deeply concerned about the quality of the last ten or twenty students accepted.

The peak of applications for admission to the medical schools of this country was in 1949-50 when 24,434 individuals applied for 7,042 places in freshman medical school classes. Last year, the number of applicants had dropped to 14,538 individuals for 7,449 places.

The University of Minnesota had 298 applicants worthy of serious consideration for 126 places; while the University of Wisconsin had 167 applicants for 82 places; Iowa, 144 applicants for 120 places; and Michigan, 512 applicants for 204 places.

The competence of the medical profession depends more upon the quality, that is, upon the ability and the character of the medical students, than upon any other single factor. It is essential, therefore, not only that medical schools be able to fill their classes with acceptable applicants, but that they be able to select students of superior qualifications.

This leads to the question as to why, in view of the splendid opportunities in medicine, there are not more young men and women applying for admission to medical schools. The answer certainly is a complex one; but two major factors are that most young men and young women do not really understand the splendid opportunities available to them in the profession of medicine, and there is a very widespread impression that it is practically impossible to gain admission to a medical school.

A high school principal in an out-state community of Minnesota recently told me that in his eight years of service in that position, not a single student had entered premedical courses, while several able young men each year entered colleges of engineering. The engineering societies of the state, he said, send a representative to his high school each year to talk to and counsel with students about opportunities in engineering, but never has anyone come to speak about careers in medicine. In fact, it was his impression that medical schools are so flooded with applications that they are not interested in receiving any more.

This being true, I would urge physicians of the state to encourage young men and women of ability and character to consider the great opportunities and satisfactions which a career in medicine can afford them. And, supplementing individual efforts, I would urge county medical societies to arrange to have representatives of the medical profession carry this message into the high schools of the state as is currently being done by engineering and other groups.

—Harold S. Diehl, *Dean*
University of Minnesota Medical School

History of Medicine in Minnesota

THE MEDICAL HISTORY OF RICE COUNTY

(1855-1901)

ADOLPH M. HANSON, M.D.
Faribault, Minnesota

"It was natural that the lamp should be a frail earthen thing in comparison to the light within, for it had not created it and only held it for a short moment."—*Pilgrim's Inn* (by Elizabeth Goudge).

This short medical history of Rice County in the State of Minnesota dates from the summer of the year 1855, when **Nathan Marvin Bemis, M.D.,** established his practice at Faribault, to and including the year 1901.

The following biographical sketch was published in the local weekly newspaper immediately following his decease:

"Nathan Marvin Bemis, M.D., the first physician to settle permanently in Faribault, was born in Whitingham, Windham County, Vermont, March 25, 1821, his ancestors being English, his father a farmer, with whom he remained until eighteen years of age. He afterwards studied medicine with Dr. Horace Smith of Wilmington, and finally attended the Vermont Medical College at Woodstock. After his graduation he practiced medicine three years in Shutesbury, Mass., and nine or ten years at Cummington, the same state. In May, 1855, he came to Faribault. Then there was but one frame house in the place, which belonged to Alexander Faribault. The Sioux were still here, and the Doctor was called upon for medical services by two of their chiefs, Papa and Red Legs. His professional rides covered a large extent of territory, and probably few physicians of the state have ridden over more miles of our country roads than he. In early life he was an abolitionist, and voted for James G. Birney. After the Republican party was formed he allied himself with that organization. Among Free Masons he was a Knight Templar, and was one of the oldest, if not the oldest Mason in the city. He has twice been Master of the Faribault Blue Lodge and Noble Grand of the Odd Fellows three times. Dr. Bemis was married February 10, 1842, his wife being Miss Emeline H. Adams, of Heath, Mass., who survives him. They have had five children, all of whom are living save one son, George O., who died when but three years of age. The four living children are Dr. J. G. Bemis, of Chicago, Ill; Mrs. W. G. Kerr, of Englewood Heights, Ill.; Mrs. H. C. Prescott and Mrs. D. N. Graves, of Faribault."

Dr. Nathan Marvin Bemis died on the 29th day of January in the year 1891. He practiced elsewhere for twelve to thirteen years and in Faribault for thirty-six years—a total of forty-eight or forty-nine years. His age at death was seventy years, nine months, and four days.

The same newspaper announcement of his death states further:

"Perhaps no resident of the county has been more widely known than Dr. Bemis. The first physician that settled in Faribault, for thirty-six years he has pursued his arduous calling, ministering to the demands of afflicted humanity of all classes with a faithfulness and devotion to duty which have commanded the respect and admiration of all who were familiar with his professional career. Only the pioneers can fully appreciate the sacrifices and personal endurance required of a physician at the early day when the Doctor commenced practice in Rice county—the response to calls at all hours of the day and night, involving the traversing of miserable apologies for roads, the crossing of dangerous sloughs, the fording of swollen streams, the braving of wintry blizzards, with the mercury far below the freezing point, while the drifting snow shrouded from sight the few landmarks by which the traveller might shape his course.

> "The Doctor was esteemed not alone for his talents as a physician, but for his many virtues as a citizen. He was a man of active intellect, and well informed in all the affairs that challenge public attention. Tho his name was often suggested in connection with public office, for which his talent and standing qualified him, he invariably declined to leave the ranks of private life. His nature was genial and kindly, and his disposition to co-operate with his fellowmen in active benevolence was manifested in his society attachments, he having been a charter member of both the Masons and the Odd Fellows organizations. At the time he joined the former there was no branch of the order in the country, and he went to St. Paul for initiation. He was also a charter member of the Knights Templars."

Dr. Nathan Marvin Bemis is the grand old pioneer of medicine in Rice county. He had that reverence for human life that made him "the lover of life (who) sees the flame in our dust and a gift in our breath." To help prolong it for others was his lifelong devotion.

Nature's nobleman, he is the grand old man of the medical profession here in Rice county. He represents that high ideal which prompts so many of our best youth to choose the healing art as life's vocation. He undoubtedly was responsible for the rather high standard of medical ethics in which the welfare of the patient was the prime consideration, and of which the medical profession in this county may rightly be proud. Despite personal differences, or even personal animosities, professional jealousies, et cetera, the Rice County Medical Society has always presented a solid front on all fundamental moral issues and has stood as one man in regard to good medical ethics. This has been so since the days of Bemis, Rose and Wood.

When Dr. Bemis arrived to establish his practice at the little White settlement in the Indian village of the Wau-pa-ku-ta Dakotas (Sioux) in May, 1855, his brother, Dr. Lewis Bemis, who came to Faribault about the 1st of March in the same year, departed for St. Paul. St. Paul, the largest white settlement in Minnesota in that year of 1855, was then a town of only 7,000 inhabitants.

Dr. Nathan Marvin Bemis, some months earlier, had debarked from a Mississippi steamboat at Hastings. He did not take the overland stage-route of 70 miles from Hastings to Faribault. He went on by a smaller steamboat to St. Paul where he had originally planned to settle down. There he heard of the little white and Indian village on the peninsula formed by the confluence of the Owatonna (Straight) River with the larger Cannon River. So, out of curiosity, the thirty-four-year-old physician took the trails leading south to look it over.

The last stage of his journey was made on the old winding road, east of the present highways, from the present site of Northfield to Faribault.

He had already fallen in love with the Upper *Mechi-sibi* (Indian: *mechi,* great; *sibi,* river), its plains, gently rolling hills and valleys, huge stands of timber, and countless lakes and streams teeming with fish. He saw what is now southeastern Minnesota as Mother Nature made it. It was then even more of a second Garden of Eden than it now is. What was more, the still young and vigorous pioneer physician fell ardently in love with the site of the village of the Wau-pa-ku-ta Dakota Indians, a tribe of the Sioux nation, the "Iroquois of the West," and decided to make it the home of self and family. And at Faribault he was to remain and to die in a bed in his own house, one of the oldest in the town of 1891, loved, respected, and mourned by people throughout Rice and adjacent counties.

As remembered by Mrs. Ina Smith, his granddaughter, still living here in Faribault, Dr. Nathan Marvin Bemis, several years before his death in 1891, had an impressive personality. Of average height and weight a little over 200 pounds, he was baldheaded on the crown, his white side-and-back locks came to his shoulders, and his enormous white beard was the talk of all who knew him. In his last years he was afflicted with a heart ailment. Because of this, and because he continued in practice despite his own affliction, his good wife would not allow him to go out alone on his professional calls. Either she, or the doctor's hired man (a young newcomer-lad by the name of Nils N. Ronning, who came to his house as a boy of seventeen), drove his horse and/or horses for him, depending upon whether town or country call. In order to have ample room for himself and his wife, a cozy body (who also weighed over 200 lbs.), and leave ample space between them for his professional bags and case of assorted drugs, his buggies were custom-built with a very wide seat. For most of his years in practice he drove a sulky drawn by a fast trotter when making his calls in town and on near-by country visits in nice summer-weather.

Mr. Nils N. Ronning, still living at age eighty-three (graduated from Faribault High School and the University of Minnesota to become a well-known editor, the author of many books, biographies, short histories, et cetera), has the following to say of Dr. Bemis, soon after he became his hired man, as the high school lad, for his board, room, and laundry, in his book entitled *Fifty Years in America:*

> "In the fall I went back to Faribault where my brother lived and had one of his congregations. I was to attend the public school and at the same time earn my room and board at the home of Dr. Bemis by taking care of his horses.
>
> "To my surprise I was given a place at the table with the family. I had expected that I was to take my meals in the kitchen.
>
> "As my English vocabulary was very limited, Dr. Bemis had some difficulty in making me understand that when he rapped at the door and said, Nils, Tom, it meant that I was to harness Tom. If there ever was a beautiful, gentle, intelligent horse, Tom was that horse. He could run very fast and he always wanted to run. Sometimes I went with the doctor out into the country. Then Tom would be given free reins. 'Have you horses in Norway that can run as fast as Tom?' the doctor would ask me. 'No, sir,' was my answer.
>
> "One day Dr. Bemis asked me to bring him something. As the weather was cold I thought he wanted the blanket. When I brought him the blanket, he tore it out of my hand, ran to the stable and brought back a whip. He cried, 'Whip, whip, whip.' Even now I know the difference between a blanket and a whip.
>
> "The doctor must have seen me standing in front of the posters announcing a circus, for he took me with him to the circus. He was an old man with white hair and a long white beard. He was a dignified man, but that day he threw dignity to the winds. We drank pink lemonade and ate peanuts; we looked at the animals, and he told me their names. If I got a 'kick' out of looking at the performances—and I did—he got a 'kick' out of watching me. When we came home, Mrs. Bemis asked me to tell her what I had seen. When words failed me, I used my hands and feet. I think I gave her a very good idea of how the clowns had acted."

This word-picture that Nils N. Ronning paints of Dr. Nathan Marvin Bemis and his good wife in their advanced years is one of two intelligent, understanding, friendly and fun-loving persons, who must have been generally loved as well as respected. With a deep understanding of human nature, in love with humanity and life, we could paint no truer picture of the ideal family doctor and the doctor's good wife.

This biographic sketch of Dr. Nathan Marvin Bemis, as the grand old man of the medical profession here in Rice county, is written in some detail as a word-picture of the medical man devoted to the art as his special calling. It is one of the medical doctor, who comes to a community, settles down to establish his practice and his home amongst the people he makes his neighbors for the remainder of his days. He was everybody's friend, willing to serve anyone who required and called for his services, whether able and/or willing to pay for them or not. And he did so to the last. He was a man who chose to wear himself out in the service of his fellow-beings in his special field of lifesaving rather than apply himself to less arduous tasks bringing higher remunerations in money.* The coldest science becomes tinged with compassion in direct personal contact with human suffering, has one but a little reverence for life—that vital principle of conscious organic life, which is the eternal mystery and marvel to the thinking mind.

In the "Official Register of Physicians, Minnesota, 1883-1890" the following licensed medical doctors practicing in Rice county in the course of those years are listed:

Name	*School*	*When Licensed*
Bemis, N. M.	Vermont Medical College, 1842	Feb. 25, 1887
Brubaker, Evans E.[1]	Starling Medical College, Ohio, 1878	Jan. 28, 1884
Coe, Samuel B.	Western Reserve, 1886	May 4, 1886
Cool, Daniel M.	Rush Medical College, 1862	Nov. 16, 1883
Coon, Hiram L.[1]	Rush Medical College, 1855	Oct. 11, 1883
Denninger, P. J.	H. Medical College, Chicago, 1887	Apr. 22, 1884
Dight, Charles Fremont	University of Michigan, 1879	Oct. 4, 1889
Gadbois, Wilfred	University of Victoria, 1887	May 11, 1887
Gibson, W. C.[2]	License by Examination	Dec. 10, 1886
Goulet, R.	University of Victoria, 1883	Mar. 21, 1885
Greaves, William[1]	University of Michigan, 1870	Oct. 11, 1883
Hunt, Wm. A.[1]	University of Michigan, 1882	Dec. 31, 1883
Jackson, R. H.	Long Island College Hospital, 1880	Nov. 16, 1883
Knight, Geo. H.	University of New York City, 1881	Oct. 13, 1883
Lynde, C. V.	Hahneman Medical College, 1883	Dec. 23, 1886
Nelson, Louis F.	University of Maryland, 1849	Nov. 12, 1883
Phillip, J. R.[3]	University of Victoria, 1884	Nov. 10, 1884
Pringle, A. F.[1]	McGill University, 1880	Mar. 10, 1885
Rockwell, C. B.	Homeopathic Medical College, 1883	Dec. 31, 1883
Rose, F. M.	Starling Medical College, 1861	Oct. 13, 1883
Seeley, J. S.	University of Michigan, 1876	Apr. 15, 1884
Wagner, C. H.	Homeopathic Hospital College, 1873	Nov. 26, 1883
Wood, George W.	McGill University, 1863	Oct. 13. 1883

---

1. Northfield
2. Morristown
3. Dundas

Faribault not specified

The first Rice County Medical Society was organized on February 27, 1867. The officers were: Dr. N. M. Bemis, President; Dr. F. H. Atkins, Secretary; Dr. H. N. Dale, Treasurer.

The other members were: John L. Scofield, Northfield; E. Lathrop, Northfield; J. W. Daniels, Faribault; Edward Everett, Faribault.

The society was reorganized on February 11, 1885, with the following officers: H. L. Coon, President; G. W. Wood, First Vice President; C. M. Cool, Second Vice President; W. A. Hunt, Secretary; R. N. Jackson, Treasurer.

In January of the year 1886, the name of the society was changed to "Cannon Valley Medical Society," because it admitted medical men in adjoining counties to membership.

---

*Nathan Marvin Bemis, M.D., attended Cole Younger and his companions at the Rice County Jail, Faribault, after their capture. He met them near Millersburg before the Northfield robbery. He recognized them at once upon his arrival at the jail to attend the wounded Cole Younger.

The Sisters at Bethlehem Academy presented him with a ring in appreciation of his attendance on them and their pupils in illness.

Biographies

Bemis, Nathan Marvin.—His professional life's story has already been told. It is, however, interesting to mark that, though he established his permanent residence and practice in Faribault in the year 1855, he did not take the time and trouble to secure his medical license until February 25, 1887. This was nearly thirty-two years later.

(Because John L. Scofield filled the place of the highly respected, grand old pioneer medical doctor in Northfield, as did his contemporary professional brother, Nathan Marvin Bemis, in Faribault, the writer deemed him worthy of mention immediately following Dr. Bemis, even though his surname does not follow in alphabetical order.)

Scofield, John Lozier.—Born in Stamford, Connecticut, on July 23, 1811. His parents, residents of New York City, were visiting friends at Stamford at the time. He graduated from the Medical School of the University of Pennsylvania (the oldest medical school in the United States having its charter from the University of Edinburgh, Scotland) in 1832. He started practice in New York City. Subsequently, he went to Jacksonville, Florida, where he remained only for a short time. From there he went to Raymond, Racine County, Wisconsin. On July 24, he married Miss Betty A. Dibble. With the exception of the two years (1849-1850) spent in California, he remained at Raymond until the year 1856, when he removed to Northfield, Rice County, Minnesota. He was Northfield's *first* and, for many years, *only* physician. Upon his arrival at Northfield, he immediately made a claim to land about four miles south of the village. He did not establish his residence at Northfield before March, 1858. Then he remained in Northfield until his death, except in 1862 to 1863 when he was assistant surgeon in the 4th Minnesota Regiment. Dr. Scofield was a member of the Legislature (1857-58). He also filled local public offices. He was Dr. Bemis' senior by ten years, and remained in Northfield to a ripe old age.

Beckwith, Edmond.—Came to Faribault in 1878, succeeding Dr. Nichols at the "Deaf and Dumb and Blind Institute." He supposedly moved to California before 1883. He died in 1915 at the age of seventy-nine.

Brubaker, Evans Edward.—He practiced in Northfield approximately between 1890 and 1909. He was born January 1, 1852, in Ohio, the son of Henry and Bea Brubaker, who originally came from Pennsylvania. Dr. Brubaker graduated from Sterling Medical College, Ohio, in 1878 and was licensed in Minnesota January 28, 1884. He and his wife, Caroline, came to Northfield soon after their marriage in Ohio. They had four sons: Delmar of Washington; Ernest of Albany, N. Y.; Howard taught in Kansas; and Walter of Milwaukee; and one daughter, Mrs. Bertha Masolf of Houston, Texas. All attended Carleton College. Dr. Brubaker died January 5, 1910, at the age of fifty-eight from carcinoma of the liver. He was buried at Northfield. Mrs. Brubaker later moved to St. Anthony Park, St. Paul, where she continued to live for many years.

Coater.—A Dr. Coater came to Rice County on May 19, 1880. No physician by that name was licensed in Minnesota and nothing more is known about him.

Coe, Samuel Buel.—Came to Minnesota in 1861 settling in Morristown. He was born in Randolph, Ohio, on August 1, 1835, and was educated at Oberlin College. His medical training he received at Rush Medical College. During the Civil War he served as assistant surgeon in the Minnesota Heavy Artillery. In

1877 he was representative in the state legislature. He may have received a degree from Western Reserve University in the 1880's. His Minnesota license certificate is dated May 4, 1886. A Morristown news item of February 9, 1887, reads: "Dr. Coe goes to Waterville Friday to assist Dr. Case in a delicate and hazardous surgical operation," indicating that he had a good medical training and that his services were in great demand. He apparently also lived and practiced in Faribault. In the 90's he practiced for many years at Fitzgerald, Georgia (he was licensed in Georgia in 1896). Later he practiced in Minneapolis. He died at his home in Rochester, Minnesota, on May 29, 1910, at the age of seventy-five.

Dr. Coe's American ancestry goes back to Robert Coe who arrived at Pilgrim Rock in 1634. His son, Dr. Henry Waldo Coe, was born in 1857. He started his education at the University of Michigan and commenced his medical studies under his father's supervision. He graduated from the Long Island College Hospital in 1880 and began practice in Mandan, then a village in Dakota Territory. He was the first physician to settle in North Dakota, west of the Mississippi. He became an important figure in medical and civic organizations. In 1891 he moved to Oregon and later specialized in nervous and mental diseases, owning and operating the Morningside Hospital. He gave outstanding services to the insane in Alaska for over twenty years. Famous is his friendship with Theodore Roosevelt which lasted until the latter's death. Dr. Coe was responsible for the bronze statues of "Roosevelt the Rough Rider" at Portland, Oregon, and Minot, North Dakota.*

Cool, Daniel M.—Practiced in Faribault from about 1890 to 1905. He graduated from Rush Medical College, Chicago, in 1861 or 1862. During the Civil War he served as surgeon in the Third Iowa Volunteer Infantry. He was licensed in Illinois in 1877, and for several years held the position of professor of diseases of children at the Chicago Medical College. In Minnesota he was licensed on November 16, 1883. For nine years he was health commissioner and for many years city physician of Faribault. He was a member of the Rice County Medical Society, the Minnesota State Medical Society and the American Medical Association. Dr. Cool died at the age of eighty-two at his home in Faribault on December 14, 1905, from heart disease after a long period of invalidism.

A **Dr. Cooley** "of Faribault" is mentioned in a St. Cloud newspaper of December 2, 1875. It mentioned that he formerly practiced in St. Cloud and that he received an offer to take charge of the St. Louis City Hospital and planned to accept it.

Coon, Hiram L.—Licensed to practice in Minnesota on October 11, 1883. In the "History of Rice County," published in the year 1882, is the following biography:

> "Hiram L. Coon, M.D., was born in Grafton, New York, on the 25th of August, 1828, and reared to agricultural pursuits. He removed with his parents to Milton, Rock County, Wisconsin, when twelve years of age, received an education at the common schools, Milton Academy, and Rush Medical College in Chicago, from which he graduated in 1854. He commenced the practice of his profession in Rutland, Dane County, Wisconsin, where he was married in 1855, to Miss Sarah Morton, daughter of Roger Morton. In 1856, he removed to Austin, this State, and in 1861 to Northfield, where he has been in constant practice since, giving special attention to surgery. He is a member of the State and also of the American Medical Societies."

---

*See "Sketches of Pioneer Physicians of Dakota County" (Dr. Henry Waldo Coe) *Journal-Lancet,* June 1, 1931, and Dr. J. Grassick *North Dakota Medicine, Sketches and Abstracts,* North Dakota Medical Association, 1926.

Cooper, J. B.—A doctor by this name "of Northfield" is mentioned in a St. Cloud newspaper item, dated April 21, 1881. It tells of his arrival in St. Cloud for the purpose of locating there. He supposedly had thorough professional experience and was a homeopath, having graduated from the Homeopathic College at St. Louis and a Hahnemann institution. He did not stay very long in St. Clould as a newspaper of August 11 of the same year tells of his leaving St. Cloud "a few weeks ago" and his association with a physician in Little Falls. Nothing could be discovered that would shed further light on his stay in Rice County.

Cummings, D. J.—Graduate of the Chicago Medical College. He came to Farmington, Dakota County, in the 50's and his card appeared in the *Dakota Weekly Journal* in June of 1856. He reported a case of leprosy which caused great excitement in Farmington. He practiced but a short time in Northfield, and returned to Farmington in 1877.

Dale, Harvey (or **Henry**) **Newton.**—Was in Rice County over half a century. Dr. Dale was born in Butler County, Ohio, August 2, 1831. He graduated from the Eclectic Medical Institute, Cincinnati, Ohio, in 1856, and settled in Rice County in the same year. As early as 1867 he resided in Faribault. He must have gone back to school as he graduated from Bennett Medical College, Chicago, in 1876. Dr. Dale died June 13, 1909, at his home in Faribault.

Daniels, Jared Waldo.—A prominent man in the medical history of Minnesota and about whom short biographies have appeared in the medical history of several counties. He was a colorful figure, well-known for his courage during the Indian Uprising. He practiced in Faribault from the fall of 1865 when he was mustered out as surgeon in the Civil War for over two years and settled there again in 1887. It is questionable whether he engaged in the private practice of medicine at this second period in Faribault. In 1900 he moved to California.

The following biography was copied from an apparently unpublished typewritten manuscript in the possession of the Historical Committee of the Minnesota State Medical Association entitled "The Biographies of St. Peter Physicians: Includes only such as came prior to 1873 and were prominently identified with the profession and the city."

"*Jared Waldo Daniels,* M.D., was born at Stratford, New Hampshire, June, 1827. His grandfather was one of the earliest and most prominent settlers of the town, and had served four years in our army in the war for American independence. The doctor received his preparatory education at the public schools and at the Lancaster Academy and was for some years a teacher. He pursued his medical studies with his uncle, Dr. Hatch, at Boston and after attending three courses of medical lectures graduated M.D. from the Bellevue Medical College, New York City.

"In March, 1855 he came to Minnesota and was appointed physician to the Upper Sioux Indians at Yellow Medicine where he was in care of the Indians belonging to that agency and the United States troops stationed there; he resigned from this position July, 1861 and removed to St. Peter and entered upon the practice of his profession.

"In 1862 he was appointed assistant surgeon in the Sixth Minnesota Infantry and was with the regiment under General Sibley in the campaign of that year. The first duty required of the doctor by Col. Sibley after joining his regiment was to establish a hospital in St. Peter for the care of those wounded at New Ulm during its defense and all others of the refugees. At that time there were over two thousand people gathered in St. Peter who had escaped from the border and many of them required medical treatment. Within forty-eight hours after the request was made by Col. Sibley, with the prompt assistance of the noble women of St. Peter, there were sixty beds in the old courthouse ready to occupy; after seeing all the wounded provided for he turned the care of the hospital over to his brother, Dr. A. W. Daniels.

"He served as special surgeon of the command under Maj. Joseph R. Brown at the battle of Birch Coulie. In this engagement twenty-two were killed, sixty wounded and eighty-seven horses killed—one-third of the entire command—and where they were thirty-six hours without food, water or sleep. Hon. Charles W. Johnson who was present at the battle, made the following statement which appears in the official record of that engagement:

> 'Assistant Surgeon, Jared W. Daniels, had accompanied Company "A" to Birch Coulie and no man on any battlefield displayed more heroism. On the morning of that fateful 2nd of September he is remembered as going about bareheaded examining and binding up the wounds of the men. He was in great personal danger but seemingly unheedful of it all, he never flinched for a moment, and for thirty-six hours he never ate a morsel of food nor closed his eyes for sleep, so great was the demand upon him.'

"In 1863 the doctor crossed the plains with General Sibley to the Missouri river and participated in the battles of Big Mounds, Buffalo Lake and Stony Lake. On his return to Minnesota he was promoted to Surgeon in the Second Minnesota Cavalry, and again crossed the plains with his regiment in 1864, joining General Sibley on the Missouri, and was with him on his march to the Yellowstone. On this campaign he was present at the battles of Kill Deer Mountain, and Bad Lands. On his return he was stationed at Fort Snelling in charge of the general hospital until he was mustered out in the fall of 1865. Soon after he located at Faribault for the practice of his profession.

"In 1868 Bishop Whipple had money placed in his hands by an act of Congress for the benefit of the Indians at Fort Wadsworth in Dakota. Doctor Daniels being well acquainted with these Indians was selected by the Bishop to go to the Fort to take charge of all supplies and look after the relief of these destitute people. The following year he was appointed by President Grant, Indian Agent for the Indians he had been in charge of the previous year. These were the Upper Sioux under Standing Buffalo who did not join the lower bands at the Lower Sioux Agency in the massacre of 1862. The Doctor established the Sisseton Indian agency, gathered them on the reservation, encouraged them to take lands in severalty, and required them to work for themselves, or at the agency, to pay for everything they received from the Government. When he left them in 1871 all had land under cultivation, were living in houses of their own building, and most of them had discarded their Indian costume; schools were established, a code of laws provided for the government of the people and officers to enforce them, and formed the first police force of Indians in the history of the Government, to patrol the reservation and the frontier, and to surpress the importation and sale of liquor.

"Dr. Daniels was transferred by President Grant to the Red Cloud Agency in Wyoming to pacify the Sioux and other hostile tribes. Here he found about five thousand Indians, consisting of Sioux, Cheyenne and Araphoes, the greater portion of them being in a turbulent state and hostile to the Government. Under the Doctor's generous treatment the number increased by others coming in from the north and south until there was over eight thousand, peaceably disposed, when he left them nearly three years later.

"In the fall of 1873 he was appointed inspector of Indian Agencies, in which capacity he visited the Agencies in Dakota, Minnesota, Montana, New Mexico and Arizona. In 1875 he was sent alone to treat with Red Cloud and Spotted Tail Indians to induce them to give up their rights in the country south of the North Platte river, after the Indian Department in Washington had failed with a delegation of these Indians called there for that purpose. He not only induced them to relinquish their rights, but dictated what they should receive in payment instead of guns and ammunition which they most urgently demanded. In the fall of 1875 he was made disbursing officer on a large Commission sent to treat with the Sioux for the Black Hills. They were unable to make a treaty. The year 1876 he was appointed on a Commission to secure the cession of the Black Hills and a treaty was affected by which the Hills were ceded to the Government. In 1886 he was again appointed on a Commission to make treaties with Indians in Minnesota, Dakota, Montana, Idaho and eastern Washington. Treaties were made with all these tribes by which many million acres of land was relinquished to the Government. He left the Government service in 1887 and returned to Faribault, where he has since resided, until two years ago, when he removed to Los Angeles, California. The Doctor is a member of the Loyal Legion Commandery of Minnesota, and the Grand Army."

DeCousens, John R.—He practiced a time in Dundas. In 1880 he made a report to the Minnesota State Board of Health of Diphtheria in Rice County covering the twelve months of 1 November, 1879-1 November, 1880. He was licensed by an exemption certificate on December 31, 1883. Probably in 1881 he moved to Lanesboro, Fillmore County, and practiced there for several years—at least until 1885 or 1886—and acted as local health officer.**

Denison, Lucius W.—Settled in Faribault about 1850 and was Representative in the Legislature 1878 to 1879. He was born in Brookfield, N. Y., on December 17, 1819.

Denninger, P. J.—A homeopath. He was born in Berlin, Germany, on January 20, 1848, and came to the U. S. with his parents in 1862. He arrived in Minnesota in 1871. Dr. Denninger graduated from Hahnemann Medical College, Chicago, in 1878. He was licensed on 22 April, 1884, and set up his shingle in Faribault this same year.† His office was in the Theopold Block. His card in the weekly newspaper stated that he paid "special attention to the treatment of chronic diseases."

Dight, Charles Fremont.—Graduate of the University of Michigan's Medical School in 1879. He was licensed in Minnesota on October 4, 1889, and came to Faribault where he established his practice. He is no doubt identical with the well-known pioneer in eugenics who fathered the Institute of Eugenics at the University of Minnesota, organized the American Eugenic Society, wrote "Eugenics," "History of the Early Stages of the Organized Eugenics Movement in Minnesota for Human Betterment," et cetera.

He was born in 1856 or 1857 at Mercer, Pennsylvania, and studied medicine at the University of Michigan. For a while he practiced in Michigan then began a career of teaching (University of Michigan, Tulane University, University of Minnesota). Six years he spent in Syria. He died in June, 1933, at the age of eighty years.

Everett, Edward.—There is no record of his being licensed to practice in Minnesota. He practiced at Paynesville, Ohio, and at Racine, Wisconsin, before the outbreak of the Civil War. He was surgeon to the 11th Wisconsin Regiment throughout the four years of the war. He came to Faribault to re-establish his practice in civil life on December 6, 1865. He either died or retired and departed Faribault before the early licenses to practice medicine in Minnesota were first issued in 1883.

**See Nora H. Guthrey, "Notes on the History of Medicine in Fillmore County prior to 1900." MINNESOTA MEDICINE, page 1141, November, 1946.

†He supposedly settled in Faribault as early as 1881, according to a history of Rice County of 1882.

(To be continued in April issue)

Public Health

RECOMMENDED PRACTICES IN THE PREVENTION OF RETROLENTAL FIBROPLASIA*

Incubator oxygen concentrations above 40 per cent are directly associated with the development of retrolental fibroplasia in prematurely-born infants. Available data indicates that the limitation of oxygen to premature infants does not increase neonatal mortality. Oxygen should not be given routinely to premature infants but for the specific indications of cyanoses and respiratory distress.

1. It is recommended that the routine administration of oxygen to premature infants be discontinued. When the physician specifically orders oxygen administration to premature infants, the incubator oxygen concentration should be kept under 40 per cent.

2. To insure incubator oxygen concentration under 40 per cent one of the following devices may be employed:

(a) Melco minus 40 per cent oxygen concentration device which is attached directly to the incubator with metal fittings and makes it impossible to administer oxygen in excess of 40 per cent concentration, regardless of oxygen flow. This is manufactured by the Melchior, Armstrong. Dessau Co., Ridgefield, New Jersey. Price, including humidifier which may or may not be used, for hospitals with piped in oxygen—
Melco 758—$48.50 F.O.B., Ridgefield. New Jersey.
For hospitals without piped in oxygen—
Melco 759—$78.00 F.O.B., Ridgefield, New Jersey.

(b) Analysis of oxygen concentration of incubator between one and two hours after turning on oxygen supply to incubator. There are two types of oxygen analyzers which are simple to operate and operate by means of contained batteries:

(1) The Mira oxygen analyzer OXA-100 is available from the Medical Instrument Research Associates, 2656 N. Pasadena Avenue, Los Angeles 31, California. Price $147.00 F.O.B. Los Angeles, California.

(2) The Arnold O. Beckman Model D oxygen analyzer is available from Arnold O. Beckman, Inc., 1020 Mission Street, South Pasadena, California. Price $190.00 F.O.B. South Pasadena, California.

(c) If the Melco minus 40 per cent oxygen concentration device is used, it is not necessary to use an oxygen analyzer. It is felt that the Melco device is more desirable and easier to use than the oxygen analyzers.

CURRENT CARDIAC CONCEPTS

The Value of Prolonged Anticoagulant Therapy

(Continued from Page 39)

coagulant therapy is far outweighed bv the benefits obtained. It must be emphasized that it should not be undertaken by any physician who is unwilling to thoroughly acquaint himself with these details, who is not fully cognizant of the hemorrhagic possibilities involved, who has not available the services of a dependable technician well trained in determining the prothrombin time, and who has a patient insufficiently intelligent and cooperative to understand the program and cooperate in its administration.

In conclusion, the use of long-term anticoagulant therapy in selected conditions is discussed and advised. It is rapidly being broadly accepted as a valuable addition to therapy. It demands meticulous care in its administration but is rewarding in the reduction of morbidity and mortality which it effects.

Miscellaneous

AMA DELEGATES' REPORT

Taciturnity, traditionally endemic to New England, isn't communicable to visitors. That is our conclusion after participating in a round of proposing, debating, resolving, commending, and condemning at this year's House of Delegates meeting in Boston. In three days, the doctors talked their way through thirty-seven resolutions and about 400 pages of reports.

Nine years ago, the AMA set up the midwinter sessions to appeal to the general practitioner—and this was his year. Several protests of general practitioners were put into one resolution which calls for:

1. AMA representatives on the Joint Commission on Accreditation of Hospitals to seek punitive action against hospitals which exclude or arbitrarily restrict hospital privileges for general practitioners as a class, regardless of their individual professional competence, after appeal to the Commission by the county medical society concerned.

2. A new and continuing Committee on Medical Practice of five members (including three general practitioners) to study the relative value of diagnostic, medical and surgical services; stimulate the formation of departments of general practice in each medical school; help the AMA's public relations department educate the public on "all of medicine"; and to "use its full influence to discourage arbitrary restrictions by hospitals against general practitioners as a group or as individuals."

There was more. After the report of the Committee on Medical Practices had been heard, the House of Delegates ordered:

1. An education program to increase the public's appreciation of non-surgical work.
2. A reappraisal of the practice restrictions of the various specialty boards.
3. That the American Hospital Association and any other interested groups be told that organized medicine is ready, willing and able to solve its own problems.

Liability Insurance Studied

The AMA committee studying professional liability insurance made a progress report. Tentative conclusions from a survey indicate that liability claims are most frequently caused by x-ray burns, foreign body left in patient after surgery, imperfect results from orthopedic surgery, failure to obtain consent prior to surgery, inaccurate prescription of drugs or improper diagnosis, criticism of one M.D. by another, excessive fees, and a poor doctor-patient relationship. The full report, due next year, should serve as a basis for action to decrease the causes and number of liability claims. If this can be done, it is reasonable to assume that this type of insurance will become more widely available at a reasonable cost.

The failure of voluntary contributions to raise sufficient funds for the American Medical Education Foundation has led to the prospect of an increase in AMA dues. The money would be earmarked for the AMEF.

Besides the delegates, representatives from Minnesota included President-elect R. H. Wilson, M.D., Winona, and R. R. Rosell, executive secretary. Others were Drs. Edgar V. Allen, Robert R. Kierland, Clark H. Millikan, Jack P. Whisnant, Howard A. Andersen, William L. Benedict, R. O. Brandenburg, Daniel C. Connolly, Victor Johnson, Byrl R. Kirklin, Frank R. Krusen, R. G. Sprague, and Edward N. Tihen, all of Rochester. Doctors Harold E. Coulter, Madelia; Harold S. Diehl, Minneapolis; Reuben Erickson, Minneapolis; J. C. Jacobs, Willmar; H. B. Sweetser, Minneapolis; Charles C. Cooper, Saint Paul, and Harry B. Hall, Edina, also attended.

Full details of the meeting will be printed in *The Journal of the AMA,* starting with the December 10 issue. Here is a brief recapitulation of some of the highlights:

AMA condemned free polio vaccine "except for those unable to pay"; distribution should be through usual channels hereafter.

A complete revision of the Principles of Medical Ethics is in the offing. The proposal will be circulated to every AMA member before the June, 1956, meeting in Chicago.

A guide for establishing local grievance committees was approved. Copies will be sent to all societies; but before a county society sets up such a committee, it is urged to contact the state secretary's office for further help and advice.

Licensure of clinical psychologists was opposed.

The AMA will get behind a new plan to interest medical men in military careers. If successful, this could eliminate need for draft.

The AMA Board of Trustees was instructed to figure out how to deal with new and unconfirmed methods of diagnosing and treating cancer. Cancer commissions run by state medical societies were suggested.

A resolution offered by the North Central Medical Conference commended Iowa physicians for their successful initial effort to establish that the

In Memoriam

SAMUEL H. BOYER

Dr. Samuel H. Boyer, Sr., former president of the Minnesota State Medical Association and pioneer Minnesota physician, died November 12, 1955. He was eighty-nine years old.

Born in Oil City, Pennsylvania, Dr. Boyer was graduated from the University of Pennsylvania medical school in 1890. He started his practice in Duluth in 1891. He was active in many civic affairs besides being a leader in his profession. He was St. Louis County coroner, and served two terms on the Duluth board of education. The system of medical examination for school children which he instituted is in force today.

Dr. Boyer had been president of the St. Louis County Medical Society and was former chief of staff of St. Luke's Hospital.

In 1950, he was presented with the Distinguished Service Award of the State Medical Association by Dr. O. J. Campbell who said:

"Dr. Samuel H. Boyer, Sr., has been an active participant in medical affairs for many years. He has been a member of the State Board of Health and was appointed a member of the Basic Science Board. He was elected president of the Minnesota State Medical Association for 1930 and has served as a councilor, a committee chairman, and as a state delegate.

"Dr. Boyer, this citation is well-deserved acknowledgment from your colleagues of the many years of meritorious service you have given to the field of medicine."

Dr. Boyer is survived by a son, Dr. Samuel H. Boyer, Jr.; a daughter, Mrs. Donald Parmalee, Beverly Hills, California, and three grandchildren.

CHARLES FAY BRIGHAM, SR.

Dr. Charles F. Brigham, Sr., who had practiced medicine in St. Cloud for fifty-two years, died October 15, 1955. He was seventy-nine years old.

Born in Lancaster, Wisconsin, Dr. Brigham moved to St. Cloud with his father, Dr. George S. Brigham, in 1878. He graduated from the University of Minnesota medical school in 1902, and interned at St. Mary's Hospital in Duluth.

He began his practice in St. Cloud in 1903. He served as city physician and at the time of his death was the oldest practicing physician in St. Cloud.

Dr. Brigham was a life member of the Minnesota State Medical Association, the American Medical Association and the Stearns-Benton County Medical Society. He was a "Fifty Club" member of the State Association. He was also a member of Nu Sigma Nu, medical fraternity.

He is survived by his wife; a son, Dr. C. F. Brigham, Jr.; and two grandchildren, all of St. Cloud. His sister, Mrs. Florence D. Colbert, lives in St. Paul.

RALPH H. CREIGHTON

Dr. Ralph H. Creighton, Minneapolis physician, died November 11, 1955, at the age of fifty-seven. He was chief of staff at Abbott Hospital.

Dr. Creighton was born in Minneapolis and practiced there from the time of his graduation from the University of Minnesota in 1923, except for a period of war service with the 34th infantry.

Dr. Creighton was chairman of the Committee on Veterans' Affairs of the Minnesota State Medical Association. He was a member of the American Medical Association and, in 1947, was president of the Hennepin County Medical Society. He was a member of the Minnesota Academy of Medicine and the American Academy of General Practice.

Non-medical groups, of which he was a member, included the Masons, Delta Upsilon and Nu Sigma Nu fraternities, the University Club and St. Paul's Episcopal Church.

Surviving are his wife; two sons, James G. of Minneapolis and John E. of Dallas, Texas, and his mother, Mrs. Clare Rees Creighton, Minneapolis.

CHARLES E. DUTTON

Dr. Charles E. Dutton, ninety-four, a member of the first class to be graduated from the University of Minnesota medical school, died Noevmber 5, 1955. Dr. Dutton, who carried on his practice in his home office in Minneapolis until recently, was the only surviving member of the class of 1889.

He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and was elected an affiliate fellow in the American Medical Association in 1929. He served as Minneapolis health commissioner in 1914 and 1915.

Dr. Dutton bought a car in 1902 and became the first physician in Minneapolis to visit country patients in a horseless carriage. He rebuilt this Locomobile Steamer, sold to him by Dr. Charles Mayo, and won a race attaining the terrific speed of 30 miles an hour. He was an early trustee of the Automobile Club of Minneapolis, president of the Minnesota Automobile Association and a director of the Twin City Motor Speedway.

Survivors include his wife, and a daughter, Mrs. Lowell M. Canfield, St. Louis Park.

REINHOLD MILTON ERICSON

Dr. Reinhold Ericson, fifty-three, died November 20, 1955. He had been an eye, ear, nose and throat specialist in Minneapolis until his retirement in 1951.

Born in Lafayette, Minnesota, Dr. Ericson was graduated from Washington University medical school, St. Louis, Missouri. He interned in Baltimore and took postgraduate work in Vienna. He was a veteran of World War II.

Dr. Ericson was a member of Westminister church, the Minneapolis Athletic Club, Lafayette Club, the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association. He was also a member of the American College of Surgeons and the International College of Surgeons.

His survivors include his wife; a son, John; a daughter, Mrs. Byron Anderson; two grandchildren, and his mother, Mrs. J. G. Ericson, all of Minneapolis.

RAYMOND F. HEDIN

Dr. R. F. Hedin, surgeon of Red Wing, died October 21, 1955, after a brief illness. He was forty-nine years old.

Dr. Hedin spent his early boyhood in Sioux City, Iowa. He attended schools in Red Wing before taking undergraduate study at the University of North Dakota. He graduated from the University of Minnesota medical school in 1930 and interned at the University Hospital. He spent a year each at Cook County Hospital and Wesley Memorial Hospital in Chicago as a resident in surgery and another year at Chicago Presbyterian as a resident in urology. During this time, he wrote a prize-winning essay on "Polypoid Disease of the Colon" which received an award from the Chicago Surgical Society.

The Goodhue County Medical Society, the Southern Minnesota Medical Association, the Minnesota State Medical Association and the American Medical Association were among his professional affiliations. In 1950, he was president of the Southern Minnesota Association. He was also a member of the Minnesota Medical Foundation, the Central Surgical Society, a fellow of the American College of Surgeons and a diplomate of the American Board of Surgery.

Dr. Hedin was active in civic affairs also. He served as mayor of Red Wing from 1945 to 1949. He was president of the Red Wing Junior Chamber of Commerce and a leader in the Democratic-Farmer Labor party.

Dr. Hedin is survived by his wife; his daughter, Barbara; three sons, Douglas, Thomas and Robert; and his mother, Mrs. Carl K. Reckner.

JOHN BURTON HOLST

Dr. John B. Holst, for many years a physician in Little Falls, died October 17, 1955, in Minneapolis. He was eighty-three years old.

Dr. Holst was born in Goodhue County in 1871. After graduating from the medical school of the University of Minnesota, he practiced briefly at Lake Benton before going to Little Falls and setting up a partnership with his brother, Dr. Fred Holst. Both retired in 1947.

He was a member of the Upper Mississippi Medical Society, the Minnesota State Medical Association and past president of the Northwest Medical Association. For many years, he was district surgeon for the Northern Pacific railway.

His daughter, Mrs. Platt Nellermoe, Wayzata, survives him. He is also survived by his brothers Henry, Austin; William, Red Wing; Alwyn, Coleraine; and a sister, Clara Holst, St. Paul.

WALTER J. MARCLEY

Dr. Walter J. Marcley, born at Franconia, Minnesota, in 1867, died November 8, 1955, in Minneapolis. He had been a pioneer and leader in the study and treatment of tuberculosis. He was one of the founders of the National Tuberculosis Association.

Dr. Marcley taught school for several years after graduating from the University of North Dakota. He then entered Boston University medical school and received his degree in medicine in 1895. He served his internship at Millard Fillmore Hospital in Buffalo and entered general practice in New York state.

In 1897, he became a student at Dartmouth College and was awarded another degree in medicine in 1902. While attending Dartmouth, he was affiliated with the Massachusetts State Sanatorium at Rutland and became superintendent of that institution.

He remained there until 1907 when he returned to Minnesota to assume direction of the Minnesota State Tuberculosis Sanatorium at Walker. In 1911, he entered private practice in Minneapolis, but remained active in the fight against tuberculosis. He was chief of the tuberculosis service at General Hospital in Minneapolis from 1912 to 1922 and medical director of Glen Lake Sanatorium from 1916 until he went to France with the Rockefeller Tuberculosis Commission. In 1919, he became chief physician for the Red Cross in Switzerland. When he returned to the United States, Dr. Marcley took over the post of Chief of the Tuberculosis Service for the Veterans Bureau at Thomas Hospital in Minneapolis and later at the Veterans Administration Hospital at Fort Snelling.

Dr. Marcley joined the medical staff at Nopeming Sanatorium and worked there from 1937 until 1941. For many years, he was on the staff of the Minnesota Department of Health as consultant in tuberculosis.

Dr. Marcley was a life member of the Minnesota State Medical Association and the St. Louis County Medical Society. He was a member of the National Tuberculosis Association, the American Sanatorium Association, the International Union Against Tuberculosis, the Minnesota Trudeau Society and the American Academy of Tuberculosis Physicians.

Survivors include his son, Dr. David M. Marcley of Amarillo, Texas, and two sisters, Mrs. Edward F. Cushman, Palmer, Massachusetts, and Mrs. Mamie Alley, Minneapolis.

SAMUEL MILLER

Dr. Samuel Miller, radiologist at Naeve Hospital in Albert Lea from 1950 to 1954, died October 12, 1955, in Jamestown, North Dakota, where he was practicing.

Dr. Miller was born in Russia in 1905. He attended St. Paul schools and received his medical education at the University of Minnesota. After his graduation in 1929, he practiced for ten years in North and South Dakota and then served for six years with the U. S. Army. He took postgraduate work in radiology at the University of Minnesota before going to Albert Lea.

He was a member of the Freeborn County Medical

Society, the Minnesota State Medical Association and the American Medical Association.

He is survived by his mother, wife, and two brothers, all of Bismarck, North Dakota.

ROBERT LYMAN NELSON

Dr. Robert L. Nelson, Duluth internist, drowned accidentally on November 12, 1955, while vacationing in Florida. He was fifty-five years old.

Dr. Nelson was born in Chicago. He attended Northwestern University medical school, graduating in 1925. He opened his practice in Duluth in 1927, specializing in internal medicine and cardiology. He was a member of the staff of St. Mary's, St. Luke's and Miller Memorial Hospitals. He was chief of staff of St. Luke's Hospital in 1951.

Dr. Nelson was a member of the St. Louis County Medical Society, the Minnesota State Medical Association, the American Medical Association, the Duluth Society of Internal Medicine, and the American Heart Association. He was a diplomate of the American Board of Internal Medicine.

Survivors are his wife; his daughter, Phyllis, Duluth; his mother, Mrs. A. M. Nelson, Chicago; a sister, Mrs. A. H. East, Chicago; and a brother, Ray.

BURT FRANK OSBURN

Dr. B. F. Osburn, physician of International Falls until he retired in 1940, died October 11, 1955. He was eighty-five years old.

Dr. Osburn was a graduate of Hamline University and the University of Minnesota medical school. He practiced in Baudette before establishing a practice in International Falls in 1919. He was administrator of the Northern Minnesota Hospital for many years.

Dr. Osburn was a member of the Upper Mississippi Medical Society and the Minnesota State Medical Association.

Mrs. Osburn is the only immediate survivor.

HENRY WILLIAM QUIST

Dr. Henry W. Quist, general surgeon of Minneapolis since 1908, died November 6, 1955, at the age of seventy-six. He collapsed on the University campus where he had planned to attend a lecture.

Dr. Quist was born in Chisago City. He attended Gustavus Adolphus College and Hamline University and graduated from the medical school of the University of Minnesota in 1907. He interned at Swedish Hospital where he later served on the staff. In 1924, he was chief of staff.

He served on the board of the American Swedish Institute, was a member of Zion Lutheran church, the Minneapolis Athletic Club, the Minneapolis Automobile Club, the Masons and the Scottish Rite.

Dr. Quist was a life member of the Hennepin County Medical Society, the Minnesota State Medical Association, the American Medical Association and was a fellow of the American College of Surgeons.

He is survived by his wife and his son, Dr. Henry W. Quist, Jr. His two sisters, Mrs. Frances Hedlund, Paynesville, and Mrs. Anna Shogren, Minneapolis; a brother, Otto, Minneapolis, and five grandchildren are other surviving relatives.

JOHN ALOIS THABES

Dr. John Thabes, fifty-four, widely-known Minnesota physician and Crow Wing county coroner for twenty years, died October 14, 1955.

Dr. Thabes was born in Brainerd and was graduated from the University of Minnesota medical school in 1925. He served his internship at St. Mary's Hospital in Duluth, and entered into practice with his father, Dr. John Thabes, Sr., in 1926.

A fellow in the American College of Surgeons, Dr. Thabes was also a member of the Upper Mississippi Medical Society, the Minnesota State Medical Association and the American Medical Association. He was a member of the Masons and the Elks.

He is survived by his wife; two sons, John, St. Paul, and Rudd, Brainerd; three daughters, Mrs. John Gilbert, Cucuta, South America; Mrs. John Schmidtke, Elgin, Illinois; and Tamara, Brainerd; four grandchildren, and a sister, Mrs. Lois Adelaide Hensley, Tulsa, Oklahoma.

HOWARD H. WOLFE

Dr. Howard Wolfe, who practiced medicine in Saint Paul from 1921 to 1940, died November 9, 1955, in San Francisco. He was fifty-five years old.

Dr. Wolfe entered the Army Medical Corps in 1940. He served for six years and then joined the Veterans Administration. He became chief medical officer of Northern California and was holding that post at the time of his death. In October, 1955, Veterans Administration officials presented him with the "exceptional service award," highest award ever given by the Administration.

He was a past commander of the Business and Professional Men's post of the American Legion in Saint Paul.

Survivors are his wife; a daughter, Mrs. Audrey Gruettenden of Los Gatos, California; a son, Dennis H. of San Francisco; and a brother, John I. of Los Angeles.

A program of research into the cause and prevention of heart disease should be undertaken on international lines under the auspices of the World Health Organization (WHO) according to the recommendations made by the WHO Study Group on Atherosclerosis which met in November in Geneva under the chairmanship of Dr. Herman Hilleboe, New York State Commissioner of Health.

The disease recommended for special investigation, "because of its paramount importance as a public health problem" is ischemic heart disease, defined by the WHO Study Group as "the cardiac disability, acute and chronic, arising from reduction or arrest of blood supply to the myocardium . . . the result of disease processes in the coronary arterial system. The main pathological processes involved are atherosclerosis and thrombosis of these vessels."

The most clearly recognized types of ischemic heart disease are myocardial infarction due to coronary obstruction (angina pectoris).—WHO News Release.

Reports and Announcements

MEDICAL MEETINGS

State

Minnesota State Medical Association, annual meeting, Mayo Civic Auditorium, Rochester, Minnesota, May 21-23, 1956.

National

Congress on Industrial Health, 16th annual meeting, Sheraton-Cadillac Hotel, Detroit, Michigan, January 23-24, 1956.

American College of Surgeons, sectional meeting, Hotel Schroeder, Milwaukee, Wisconsin, February 27-29, 1956. Dr. Forrester W. Raine, Milwaukee, chairman.

Atlanta Graduate Medical Assembly, Biltmore Hotel, Atlanta, Georgia, February 20-22, 1956.

Mediclinics of Minnesota, postgraduate course sponsored by Academy of General Practice of Broward County, Fort Lauderdale, Florida, March 5-14, 1956.

INTERNATIONAL COLLEGE OF SURGEONS

Regional Meetings

Four regional meetings of the United States and Canadian Sections, International College of Surgeons, are scheduled for 1956.

The first, the Mid-Atlantic Region, meeting will be held at the Green Brier Hotel, White Sulphur Springs, West Virginia, February 13-15. This will be followed by a meeting March 22-23 in San Jose, California. A Southeastern regional meeting will be held in the Read House, Chattanooga, Tennessee, April 30-May 1, and a New England regional meeting in the Marshall House, York Harbor, Maine, over the July 4 weekend.

In Chicago on September 9-13 the Tenth Congress of the International College of Surgeons will be held in conjunction with the Twenty-First Congress of the United States and Canadian sections. Headquarters will be in the Palmer House.

For further information, write the Secretariat of the United States Section, International College of Surgeons, 1516 North Lake Shore Drive, Chicago 10, Ill.

Examinations for Fellows

Four oral and four written examinations for Fellows in the United States Section of the International College of Surgeons will be conducted in 1956.

Oral conferences will be held on January 23, April 16, August 6 and October 22. The written examinations will be conducted on January 30-31, April 23-24, July 23-24 and October 29-30. These will be held at the Cook County Hospital and Cook County Graduate School of Medicine, Chicago.

PAN AMERICAN MEDICAL WOMEN'S ALLIANCE

The Fifth Congress of the Pan American Medical Women's Alliance will be held in Santiago and Vina del Mar, Chile, March 6 to 13, 1956. Also planned is a trip to include visits to hospitals and medical clinics in Mexico, San Salvador, Panama, and southern Chile under the guidance of some of the Chilean women doctors. Following the Congress a week will be spent in La Paz, Bolivia, visiting medical projects among the Incas. En route to Lima, there will be a trip across Lake Titicaca and ample opportunity to explore the archeologic treasures of Cuzco and Macchu Picchu.

Program chairman is Dr. Eva Cutright, Wooster, Ohio.

AMERICAN ACADEMY OF GENERAL PRACTICE

The Eighth Annual American Academy of General Practice Scientific Assembly will be held March 19-22, 1956, in the Washington, D. C., Armory.

During the four-day scientific meeting twenty-six outstanding speakers will discuss subjects ranging from cardiac emergencies to primary wound repair. There will be more than 60 scientific and 250 technical exhibits. Highlights of the program will include two live clinics, a symposium on obstetrics and an address by Surgeon General Leonard Scheele. Special tours through the National Institutes of Health, Bethesda, Maryland, have been arranged.

AMERICAN INSTITUTE OF DENTAL MEDICINE

The American Institute of Dental Medicine continues to offer Case Histories from the broad field of dental medicine for the year 1955-56. These include original 35 mm. Kodachrome slides of the oral condition, pertinent laboratory findings, medical background, roentgenograms, histologic slides, photomicrographs, diagnostic criteria and whatever else may be indicated in each individual case. A loose leaf binder and matching Kodachrome slide box are furnished each participant.

For further information write the Secretary, Mrs. C. Novembri, 2240 Channing Way, Berkeley 4, California.

HAWAII MEDICAL ASSOCIATION

Hawaii Medical Association, 100th anniversary meeting, Honolulu, Hawaii, April 22-29, 1956. For reservation applications, write Hawaii Medical Association, 510 South Beretania Street, Honolulu 13, Hawaii.

General Practice Review, postgraduate course sponsored by clinical departments and Office of Postgraduate Medical Education, University of Colorado Medical Center, 4200 East Ninth Avenue, Denver 20, Colorado, January 16-21, 1956.

CLINICAL REVIEWS AT MAYO CLINIC

A three-day program entitled Clinical Reviews will be held by the Mayo Clinic and Mayo Foundation at Rochester, April 9, 10 and 11. The program will consist of lectures and discussions on problems of general medicine and surgery. Presentations will be made by staff members of the Mayo Clinic and Mayo Foundation for Medical Education and Research.

The number of physicians who can be accommodated is limited. For further information, write R. C. Roesler, Mayo Clinic, Rochester, Minnesota. There are no fees for the session.

MINNEAPOLIS OBSTETRICAL AND GYNECOLOGICAL SOCIETY

The Minneapolis Obstetrical and Gynecological Society was organized at a dinner meeting held at the Minneapolis Club the evening of October 26, 1955. Officers elected at that time are: John A. Haugen, M.D., President; Rae T. La Vake, M.D., Vice President; and Francis M. Swain, M.D., Secretary-Treasurer. John L. McKelvey, M.D., and James Shandorf, M.D., were elected to serve with the officers on the Executive Council.

Present plans include holding meetings four or five times during the year.

CONTINUATION COURSES

The University of Minnesota announces a continuation course in *Eye, Ear, Nose, and Throat for General Physicians* which will be presented at the Center for Continuation Study from February 27 to 29, 1956. The most commonly seen problems in this field will be discussed and treatment will be stressed. The course will be presented under the direction of Dr. L. R. Boies, clinical professor and head of the Department of Otolaryngology, and Dr. Erling W. Hansen, clinical professor and head of the Department of Ophthalmology.

* * *

The University of Minnesota announces a continuation course in *Dietetics for Dietitians* at the Center for Continuation Study next March 1 to 3, 1956. Recent advances in the field will be stressed. The course will be presented under the direction of Miss Angeline D. Mannick, director of nutrition and associate professor of dietetics.

* * *

A continuation course in *Pediatrics for General Physicians* will be presented by the University of Minnesota at the Center for Continuation Study on March 5 to 7, 1956. Guest faculty will include Dr. Katharine Dodd, professor of pediatrics, University of Arkansas School of Medicine, who will also deliver the annual Phi Delta Epsilon Lecture on Tuesday evening, March 6. The course will be presented under the direction of Dr. John A. Anderson, professor and head, Department of Pediatrics.

* * *

The University of Minnesota, in conjunction with the Minnesota Heart Association, will present a continuation course in *Cardiovascular Disease for General Physicians* at the Center for Continuation Study from March 19 to 21, 1956. Management of the more frequently seen cardiovascular disorders will be stressed. Guest speaker will be Dr. Hans Hecht, Associate Professor of Medicine, University of Utah College of Medicine, Salt Lake City. The course will be presented under the direction of Dr. C. J. Watson, Professor and Head, Department of Medicine.

F. H. Magney, M.D., Secretary

MONTEVIDEO MAN SENTENCED ON ABORTION CHARGE

Re: State of Minnesota vs. Omer Peterson

On December 5, 1955, Omer Peterson, thirty-six, 913 N. Fourth Street, Montevideo, Minnesota, was sentenced in district court there by the Hon. Sam G. Gandrud, Judge of the District Court, to a term of not to exceed four years in the State Reformatory for Men at St. Cloud, Minnesota, pursuant to his plea of guilty to an information charging him with the crime of abortion, which plea had been previously entered before Judge Gandrud on October 17, 1955. The execution of the sentence was stayed, however, and the defendant was placed on probation in the custody and control of the State Board of Parole. One of the conditions of the probation prescribed by the Court was that Peterson shall be of good behavior and comply with and abide by all the rules and regulations that may be prescribed by the State Parole Board or any of its agents.

The defendant was arrested at Montevideo on July 5, 1955, and charged with the crime of abortion in a complaint issued on the same date, after a twenty-three-year-old Minneapolis divorcee had been hospitalized at University Hospital in Minneapolis suffering from the aftereffects of an abortion. In a signed statement given to the authorities, Peterson, who said that he was a salesman for an air-conditioning and heating firm, admitted that he had attempted to perform an abortion upon the same woman about a year or two previously in Sioux Falls, South Dakota, by using a plastic drinking tube about 10 inches long. According to the defendant's statement, a similar instrument was used in performing the most recent abortion, which took place in a Montevideo hotel room on June 20, 1955. Peterson was paid the sum of $50.00 for his services in connection with this case. The defendant has no medical training and holds no license to practice any form of healing in the State of Minnesota.

AMA DELEGATES' REPORT

(Continued from Page 62)

practice of medicine (pathology and radiology) by hospitals is illegal.

AMA will ask the Federal Government to regulate safety standards of automobile construction.

Interim Session in Minneapolis

The Board of Trustees has accepted the invitation of the North Central Medical Conference to hold the Interim Session of 1958 in Minneapolis. This will be a splendid opportunity for large numbers of doctors in the upper Midwest to attend one of the clinical meetings.

J. Arnold Bargen, M.D., Rochester
George Earl, M.D., Saint Paul
O. J. Campbell, M.D., Minneapolis

Woman's Auxiliary

RADIO AS A PUBLIC HEALTH SERVICE

Mrs. O. M. Heiberg, Worthington

"Does Johnny Make the Team?", "Rabies," "Mental Health in Child Development," and "The Promise of Geriatrics" are among the various subjects discussed on "Your Health Hour," a 15-minute health information program on the air each Sunday afternoon, over radio station KWOA, Worthington, Minnesota.

This program is the outgrowth of the first rural "Health Day" held in Worthington, Minnesota, in February, 1949. The Southwestern Minnesota Medical Society, together with its Woman's Auxiliary and District V of the Minnesota Department of Health, have just completed seven years of weekly broadcasts as a public service to the community.

A committee composed of doctors, auxiliary members, and the advisory nurse of District V, Minnesota Department of Health, meet quarterly to plan the programs. Live broadcasts are used as well as "platters" obtained from the American Medical Association.

In planning the content of the programs, the particular interests of the six-county area are given consideration. For example, an outbreak of rabies in the area gave accent to a broadcast on that subject. Brucellosis is also of special interest here, so a program on that subject seemed pertinent. Since there is usually some National Health emphasis each month, a program on the monthly theme being sponsored with a live broadcast using a physician, nurse and/or layman from the area. The three organizations also give support to the school health program and co-operate with the school health councils by giving timely broadcasts on subjects at their request. When local groups are promoting Mantoux and Brucellosis tests, pasteurization of milk, safety programs, et cetera, the group has been on hand with live broadcasts to further emphasize the value of these public health services.

Using spot announcements to list the radio programs and the speakers has been the most effective method of alerting the listening audience to the programs. Posters have been used in physicians' offices, hospitals, and public meeting centers; but as they are seldom kept up to date, they are not being used at present.

Doctors and nurses, as well as lay people, have been enthusiastic and willing to co-operate when requested to participate in live broadcasts.

When the Minnesota Department of Health is able to provide a script writer and live broadcasts are used, the interest is much greater. This is shown in the number of letters and comments brought to the attention of the committee.

In summary, this broadcasting project has been a great success and well worth the effort. It is with pleasure that the Worthington group announces an expansion of the program. On January 8, 1956, the Southwestern Minnesota Medical Society, its Woman's Auxiliary, and District V of the Minnesota Department of Health congratulated Station KLOH, Pipestone, Minnesota, on starting a similar Sunday afternoon program to be called "Your Health Hour."

RAMSEY COUNTY AUXILIARY NEWS

Mrs. Lucian G. Culver, Saint Paul

Members of the Ramsey County Medical Auxiliary have been busy the past month assisting the Fourth District Nurses with their Nursing Recruitment Program. Their part in the program was to drive the student nurses to the various junior and senior high schools in Saint Paul.

Twice a year, student nurses from the different hospitals in Saint Paul present a panel discussion to these students. The purpose of the program is to acquaint the students with the various types of nursing. The panel consists of a moderator and a student from each class of the nursing profession. This includes the practical nurse, the three-year nurse and the degree nurse.

Mrs. R. K. Grau, chairman of the career committee for the auxiliary, reports that the students are very much interested in this program, and many students have been recruited on the strength of it.

The month of December is the time for the Christmas Seal sale throughout the country. A great many auxiliary members volunteered to staff Christmas Seal sale booths in the downtown area on the day specified for the auxiliary.

Speaking of Christmas Seals, four Ramsey County Auxiliary members participated in the quiz program devoted to the Christmas Seal sale which appeared on the "Cash and Carry" program on KSTP television recently. Twenty dollars, collected by the clever foursome, was donated to the Tuberculosis Association.

LABORATORY AIDS

Acute Infectious Hepatitis

(Continued from Page 38)

of serum. If at that time less than 5 per cent of sulfobromophthalein is retained in 45 minutes, the patient may resume normal activity. These two tests are repeated after two to four weeks.

3. If retention of the dye becomes stabilized consistently at 5 to 10 per cent, the patient may be dismissed. If values remain increased or if they fluctuate, individualized management in each case is indicated. Hepatic biopsy may be necessary.

4. Abnormal results of liver function tests may recur after they have become normal. The patient may have to be reconfined in such instances.

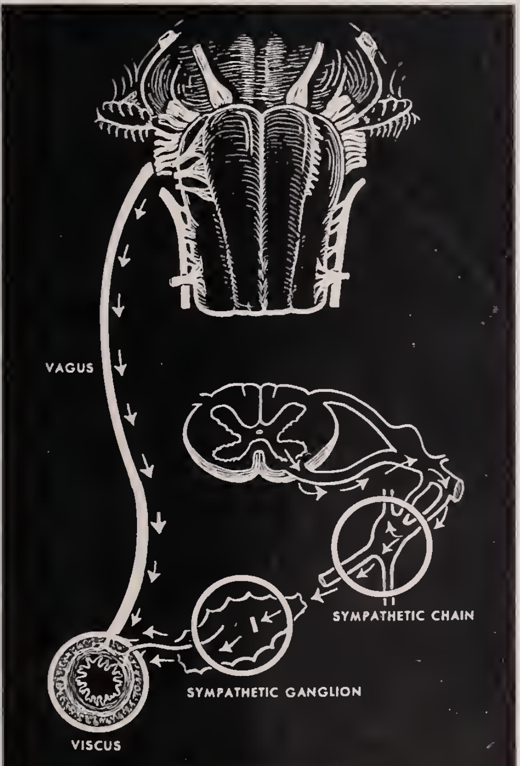
PRO-BANTHĪNE® FOR ANTICHOLINERGIC ACTION

A Combined Neuro-Effector and Ganglion Inhibitor

Pro-Banthīne consistently controls gastrointestinal hypermotility and spasm and the attendant symptoms.

Pro-Banthīne is an improved anticholinergic compound. Its unique pharmacologic properties are a decided advance in the control of the most common symptoms of smooth muscle spasm in all segments of the gastrointestinal tract.

By controlling excess motility of the gastrointestinal tract, Pro-Banthīne has found wide use[1] in the treatment of peptic ulcer, functional diarrheas, regional enteritis and ulcerative colitis. It is also valuable in the treatment of pylorospasm and spasm of the sphincter of Oddi.



Sites at which Pro-Banthīne inhibits excess autonomic stimuli through control of acetylcholine mediation.

Roback and Beal[2] found that Pro-Banthīne orally was an "inhibitor of spontaneous and histamine-stimulated gastric secretion" which "resulted in marked and prolonged inhibition of the motility of the stomach, jejunum, and colon. . . ."

Therapy with Pro-Banthīne is remarkably free from reactions associated with parasympathetic inhibition. Dryness of the mouth and blurred vision are much less common with Pro-Banthīne than with other potent anticholinergic agents.

In Roback and Beal's[2] series "Side effects were almost entirely absent in single doses of 30 or 40 mg. . . ."

Pro-Banthīne (β-diisopropylaminoethyl xanthene-9-carboxylate methobromide, brand of propantheline bromide) is available in three dosage forms: sugar-coated tablets of 15 mg.; sugar-coated tablets of 15 mg. of Pro-Banthīne with 15 mg. of phenobarbital, for use when anxiety and tension are complicating factors; ampuls of 30 mg., for more rapid effects and in instances when oral medication is impractical or impossible.

For the average patient one tablet of Pro-Banthīne (15 mg.) with each meal and two tablets (30 mg.) at bedtime will be adequate. G. D. Searle & Co., Research in the Service of Medicine.

General Interest

Minnesota physicians are invited to submit items of "general interest" concerning themselves or their colleagues to MINNESOTA MEDICINE, 2642 University Avenue, Saint Paul. Only the facts are needed—who? what? where? when? why?—since items will be rewritten for conformity of style.

* * *

Dr. J. Arnold Bargen, head of a section of medicine at the Mayo Clinic, Rochester, and professor of medicine in the Mayo Foundation, has been elected president of the staff of the Mayo Clinic. Other officers elected at the annual meeting of the staff on November 21 include **Dr. Winchell McK. Craig,** vice president; **Dr. David G. Pugh,** re-elected secretary, and **Dr. Kendall B. Corbin** and **Dr. L. O. Underdahl,** councillors. Named to the board of governors were **Dr. Mark B. Coventry** and **Dr. William H. Dearing.**

* * *

Dr. E. C. Burseth, Mora, was elected president of the Mora Commercial Club at the organization's meeting on November 14.

* * *

Dr. S. Marx White, Minneapolis, has submitted his resignation as a member of the Glen Lake Sanatorium commission. He served on the commission for thirty-one years.

* * *

Principal speaker at a meeting of the Rotary Club in Little Falls on November 17 was **Dr. G. M. A. Fortier,** Little Falls. He discussed the contributions made by laymen to modern medical science.

* * *

Dr. H. F. Helmholz, Sr., Rochester, emeritus member of the pediatrics staff of the Mayo Clinic, has been named to a committee to outline plans for a state organization for better recognition and encouragement of exceptional talent in Minnesota youngsters.

* * *

During the middle of November, **Dr. H. P. Hinderaker,** Bird Island, attended a two-week postgraduate course at the Cook County Graduate School of Medicine, Chicago.

* * *

Dr. O. E. Wandke, Fairmont, was elected president of the Blue Earth Valley Medical Society at a meeting in Blue Earth on November 17. Other officers named include **Dr. H. E. Coulter,** Madelia, vice president, and **Dr. Herbert Boysen,** Madelia, secretary-treasurer.

* * *

Main speaker at the annual meeting of the Southern Minnesota Vegetable Growers Association in Albert Lea on November 29 was **Dr. Charles W. Mayo,** Rochester. The title of his address was "A Forward Look Toward Peace."

* * *

Dr. P. C. Hedenstrom has been elected president of the medical staff of Weiner Memorial Hospital at Marshall. Named as vice president of the staff was **Dr. T. C. Kreuzer,** and as secretary-treasurer, **Dr. J. E. Murphy.**

* * *

Dr. George M. Higgins, Rochester, senior consultant in the section of anatomy at the Mayo Clinic, retired on December 31. Dr. Higgins, who joined the Mayo Clinic in 1924, has published more than 200 original studies, primarily in fields of experimental biology.

* * *

Dr. Charles A. Corse, Kelliher, celebrated his eighty-second birthday anniversary on December 10. Dr. Corse began the practice of medicine in Verndale in 1897. For the past forty years, he has lived at Kelliher. He retired from active practice in 1941.

* * *

At the annual meeting of the Minnesota Obstetrical and Gynecological Society in Saint Paul recently, **Dr. R. F. Sturley,** Saint Paul, was elected president. Other new officers of the group include **Dr. Frederick Schade,** Worthington, vice president, and **Dr. E. A. Banner,** Rochester, secretary-treasurer.

* * *

Principal speaker at a meeting of the Lions Club in Crookston on November 14 was **Dr. C. L. Oppegaard** of Crookston, who gave an illustrated talk on a recent trip he made through Mexico.

* * *

Dr. M. J. Schirber, Grand Rapids, was moderator of a panel discussion on "The Place of the Hospital in the Community" at a meeting of the Tenth District Nurses Association at Grand Rapids on November 14.

* * *

Mahnomen lost both of its physicians in mid-December. **Dr. K. W. Covey,** who has practiced at Mahnomen for eleven years, announced last summer that he had accepted a residency in orthopedics at the Mayo Clinic, Rochester, beginning January 1. He closed his office in Mahnomen on December 17. **Dr. J. M. Gacusana,** who has practiced at Mahnomen since 1953, closed his office on December 15 and moved to Akron, Iowa. Dr. Gacusana stated that his decision to leave was influenced by the belief that "I cannot do justice to a medical practice without hospital facilities"—doubtless referring to a decision of the Sisters of St. Benedict to close St. Anthony's Hospital at Mahnomen on December 1.

* * *

Dr. and Mrs. P. R. Lipscomb, Rochester, returned late in November from a three and one-half week trip to Hawaii, during which Dr. Lipscomb was a guest speaker at a meeting of the Western Orthopedic Association.

* * *

Dr. S. J. Raetz, Maple Lake, discussed the diagnosis of cancer when he appeared as the principal speaker at a meeting of the Lions Club at Maple Lake in mid-November.

Dr. John A. Jensen was married to Gloria Natalie Baalson at the Valley Grove Lutheran Church at Nerstrand on November 5. Dr. Jensen is a member of the staff of the Crookston Clinic, Crookston.

* * *

Dr. Nellie O. Barsness, Saint Paul, has been named "Medical Woman of the Year" by the Minnesota branch of the American Medical Women's Association. Dr. Barsness, who specializes in ophthalmology and otolaryngology, has practiced medicine since 1902.

* * *

Principal speaker at a meeting of the Business and Professional Women's Club in Hutchinson recently was **Dr. C. G. Sheppard,** health officer at Hutchinson. He spoke on the subject, "Public Health."

* * *

Dr. David A. Sher, Virginia, was elected president of the Range Medical Society at a late fall meeting of the organization. Elected secretary-treasurer of the group was **Dr. D. J. Richter,** also of Virginia.

* * *

Dr. Ezra V. Bridge, superintendent and medical director of Mineral Springs Sanatorium, Cannon Falls, has been elected a trustee of the Upper Midwest Hospital Conference as a representative of the Minnesota Hospital Association.

* * *

The role of nursing in connection with mental health was the subject of a talk given by **Dr. Dale Cameron,** medical director of the Minnesota Department of Public Welfare, at a meeting of the Saint Paul District Nurses Association in Saint Paul in mid-November.

* * *

At a meeting of the Association of Fellows of the Mayo Foundation in Rochester on December 2, **Dr. Thomas E. Lynn,** a fellow in surgery from Dubuque, Iowa, was elected president to replace **Dr. Edward J. Sanders** of Omaha, Nebraska. Elected vice president was **Dr. Robert G. Stevens** from Wellsboro, Pennsylvania. **Dr. Frank M. Pearce,** from Ballinger, Texas, was named secretary, and **Dr. Louis B. Matthews** of Jackson, Tennessee, was elected treasurer.

* * *

Dr. Troy Rollins spoke on "Medical Work Among the Indians in Northern Minnesota" at a meeting of the Sixth District Nurses Association at the Rochester State Hospital on November 14.

* * *

Physicians held the spotlight at the Duluth Industrial Safety School Conference in Duluth on December 14. General speaker for the conference was **Dr. Charles W. Mayo,** Rochester, who spoke on "Living Safely." Section speakers at the conference included **Dr. John E. Power, Jr., Dr. John Peterson, Dr. William Klein** and **Dr. Frank J. Hirschboeck,** all of Duluth, and **Dr. Joseph Bloom,** Silver Bay. The safety school, which was open to the public, was sponsored by the Duluth Chamber of Commerce industrial safety committee.

* * *

Dr. Waltman Walters, head of a section of surgery in the Mayo Clinic and professor of surgery in the Mayo Foundation, has been advanced to the grade of rear

admiral in the U. S. Naval Reserve. He has been a member of the reserve since 1936.

* * *

Dr. Harry B. Zimmermann, retired chief of the medical staff of Miller Hospital, Saint Paul, was honored by 100 of his colleagues at a gathering in Saint Paul on November 18. A memorial plaque that will be mounted on the new Harry B. Zimmermann wing of Miller Hospital was unveiled at the meeting, and Dr. Zimmermann was presented with a silver plate. Speakers included **Dr. Frederic Foley, Dr. N. Logan Leven** and **Dr. Owen Wangensteen.** Dr. Zimmermann, who has been in practice for forty-five years, was chief of staff at Miller Hospital from 1941 to 1949.

* * *

Dr. William Sawyer Eisenstadt, Minneapolis, presented a paper entitled "Osteoporosis and Compression Fractures from Prolonged Cortisone and Corticotropin Therapy" at the second International Congress of Allergy in Rio de Janeiro, Brazil, November 6 to 13. Co-author of the paper was **Dr. Ephraim B. Cohen**, Minneapolis.

* * *

Dr. Albert Faulconer, Rochester, was elected a member of the board of directors of the American Board of Anesthesiology at a meeting in New York this past fall. He succeeds **Dr. John S. Lundy**, Rochester, who vacated the office after serving for seventeen years.

* * *

Dr. Robert W. Huber, Taylors Falls, has become a member of the Braham Community Hospital staff, serving as radiologist for the hospital two days per week.

NEW LOCATIONS

Dr. N. E. Fidelman has opened offices for the practice of medicine at Foley. He previously practiced there for four years before leaving for military service in 1953.

* * *

Dr. Willard H. Peterson has joined the staff of the medical department of Geo. A. Hormel & Co., Austin. The department has two other full-time physicians, **Dr. Tracy Barber** and **Dr. Donald O. Osborn.** Dr. Peterson had previously practiced at Spring Valley since 1950.

MINNESOTA BLUE SHIELD-BLUE CROSS

In comparing the Blue Shield statistical data for the month of October, 1955, with those of the same month in 1954, and the first ten months of 1955 with the same period of 1954, increases are apparent in the amount paid for claims by Blue Shield, in the number of services for which Blue Shield provided payment, and in enrollment of participant subscribers.

During the month of October, 1955, Blue Shield provided payments in the amount of $504,988 for doctors' services rendered participant subscribers. This figure represents an increase of $87,839 over the amount of $417,149 which was paid by Blue Shield in October of 1954, an increase of 21 per cent.

From January 1 through October 31, 1955, Blue Shield provided payments in the amount of $4,757,876 for services rendered Blue Shield subscribers, or $650,779 more than was paid during the same period in 1954. During the first ten months of 1954, Blue Shield paid $4,107,097 for services rendered participant subscribers. These figures represent an increase of approximately 15 per cent in the amount paid by Blue Shield for care of subscribers during the first ten months of 1955 as compared with the amount paid during the same period of 1954. The Blue Shield claims cost for the first ten months of 1955 is only $212,355 less than the amount paid during the entire year of 1954, when Blue Shield paid $4,970,231 for care of subscribers.

The number of doctors' services for which Blue Shield provided payments during the first ten months of 1955 is 165,536. This figure is 25,419 greater than the number of services paid by Blue Shield during the first ten months of 1954, representing an increase, percentagewise, of over 18 per cent.

In the ten-month period from January 1 through October 31, 1955, Blue Shield enrollment increased from 670,757 subscribers to 717,097 subscribers, representing a ten-month enrollment increase of 46,340 participant subscribers.

During the month of October, 1955, 84,244.8 days of hospital care were provided for 13,931 Minnesota Blue Cross participant subscribers. Compared to October, 1954, this represented an increase of 951 cases and 4,526.2 days of hospital care. There were several factors contributing to this increase. As of October, 1955, there were 384,721 Blue Cross contracts in effect compared to 377,747 as of October, 1954. There was a noticeable increase in certain types of cases. Digestive diseases showed an increase of 233 cases representing 1,071.0 days of patient care. Accident cases showed an increase of 221 cases, representing 1,563.8 days of patient care. Genito-urinary diseases showed an increase of 155 cases representing 240.2 days of patient care. Respiratory diseases showed an increase of 148 cases representing 645.5 days of patient care.

As of October 31, 1955, Blue Cross provided 850,282.6 days of hospital care for 138,880 subscribers compared to 831,496.8 days for 138,582 subscribers for the same ten months period in 1954 . . . or an increase of 298 cases and 18,785.8 days of patient care.

One of the contributing factors to the increased average of hospital days per case is the decrease in respiratory illnesses . . . primarily tonsillectomies.

There was also a decrease in the number of medical respiratory illnesses . . . 9,468 cases paid during the first ten months of 1955 compared to 10,372 cases paid during the same period in 1954.

The average length of hospital stay for obstetrical and medical care remained at 4.8 days and 6.4 days per case, respectively. The average stay for surgical care increased from 6.0 to 6.4 days . . . thus the effect of the decrease in number of tonsillectomies.

It is interesting to note that Blue Cross benefits for digestive diseases approximated $3,000,000 during the first ten months of 1955; obstetrical benefits exceeded $2,600,000; benefits provided for circulatory diseases nearly $2,000,000; benefits for genito-urinary diseases exceeded $1,600,000.

CAL-ZO
. . . still the
best all-purpose
DRESSING OINTMENT

CAL-ZO
CALZO DRESSING OINTMENT
ULMER PHARMACAL COMPANY

CAL-ZO, originally prepared as the most suitable dressing ointment for pressure-sponge ambulatory treatment of varicose ulcers, continues as the ointment of choice for dressings of every nature. CAL-ZO is ideal whenever calamine and zinc oxide are indicated.
CAL-ZO provides a semi-fluid cushion at body temperature thus protecting lesions under treatment. Contact between gauze threads and seeping surfaces is prevented. Non-caking, it will not interfere with the healing lesion. CAL-ZO, because of its special base, will not soak into dressing at body temperatures. Easy to apply, CAL-ZO is the choice of the clinician when all-purpose dressing ointments are considered. Available in 1 oz. or 1¼ lb. jars. MM-156.

Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

SHOULD THE PATIENT KNOW THE TRUTH? A Response of Physicians, Nurses, Clergymen, Lawyers. Edited by Samuel Standard, M.D., and Helmuth Nathan, M.D. 160 pages. Price, $3.00. New York: Springer Publishing Co., Inc., 1955.

After reading this book, my conclusion is that any patient of mature age should know the truth, if he or she asks for it.

There are spiritual and material values that are their responsibility. The contentment that comes from meeting these responsibilities far exceeds the worry of uncertainty. Everyone knows he has to die.

WM. R. BAGLEY, M.D.

CLINICAL DISORDERS OF HYDRATION AND ACID-BASE EQUILIBRIUM. By Louis G. Welt. 262 pages. Price, $6.00. Boston: Little, Brown & Company, 1955.

This is a praiseworthy book. In concise and orderly form, the author presents a comprehensive and stimulating review of his subject. The first part of the book is devoted to physiologic considerations, including a discussion of volumes and composition of body fluids, the dynamics of body water and electrolytes, acid-base relationships, renal physiology, and a brief but excellent chapter describing the consequences of expansion and contraction of the body fluids. Part two is devoted to clinical considerations, including a discussion of maintenance requirements, the use of parenteral fluids, dehydration, acid-base imbalance, edema, and acute renal insufficiency.

The book is well written and the diagrams are simple and pointed. The conciseness and clarity of this monograph is clearly dependent upon the author's unique approach. Rather than discuss in detail the various diseases which cause fluid and electrolyte disorders, Doctor Welt has considered the subject as it relates to homeostasis of body fluids in all circumstances, as regards volume, tonicity, composition, and pH. Thus, using fundamental principles and ideas acquired by a careful study of this book, the reader is able to evaluate and treat properly almost any disorder of fluid and electrolyte metabolism.

The reviewer does not hesitate to recommend a careful reading of this book by teachers and practitioners of medicine and surgery, as well as by undergraduate students.

ROBERT J. GOLDISH, M.D.

Classified Advertising

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, *2642 University Avenue, Saint Paul 14, Minnesota.*

WANTED—Obstetrician and pediatrician for new Minneapolis group. Opportunity unsurpassed. Must apply at once. Address E-500, care Minnesota Medicine.

WANTED—Young General Practitioner, also young Internist to join small group consisting of Pediatrician, General Practitioner and General Surgeon in Minneapolis. Building is entirely new and designed for group practice. Address E-504, care Minnesota Medicine.

Sick patients

need food for therapy

Sustagen

Therapeutic Food for
Complete Nourishment

THAT MAN MUST EAT to remain well is a concept as old as medicine. But only recently has it been established (1) that nutritional needs are increased in illness; (2) that food sufficient to meet these needs is well utilized, and (3) that therapeutic nutrition prevents many of the debilitating effects of disease and injury.

Unfortunately, because of the anorexia accompanying illness, effective nutritional therapy requires added care on the part of the physician. Food comes from familiar kitchens and lacks the impressive aura of more dramatic therapeutic agents. Thus it is often difficult to convince the patient that food, too, is therapeutic —that although drugs may arrest disease only food can repair the ravages of disease.

Whatever the nutritional problem—whether caused by anorexia, mechanical difficulty in eating or limitation of gastric capacity or tolerance—only an assured food intake will solve it. The use of Sustagen, a food formulated for therapeutic nourishment, will overcome many difficulties in the therapeutic feeding of sick patients. A foundation for therapy thus may be established.

The development of Sustagen exemplifies the continuous effort of Mead Johnson & Company to provide the medical profession with products basic to the management of illness and the restoration of health.

Sustagen® is the only single food which contains all known nutritional essentials: protein, carbohydrate, fat, vitamins and minerals. It may be given by mouth or tube as the only source of food or to fortify the diet in brief or prolonged illness.

Sustagen

repairs tissue
restores appetite
overcomes asthenia

Tonsillitis, pharyngitis quickly yield to

ILOTYCIN

(Erythromycin, Lilly)

Temperature rapidly returns to normal; swelling and soreness readily subside. Notably *safe* and well tolerated.

dosage: Usually, 250 mg. q. 6 h. Children, 5 mg. per pound of body weight q. 6 h.

Lilly

532200

YOU MEAN YOU HAD TO PAY TWENTY-FIVE DOLLARS FOR THOSE NEW MEDICINES?
YES... BUT THEY SAVED $900 AND MY HUSBAND'S LIFE!

YEARS AGO when the physician fought to bring a patient through a siege of pneumonia there was little he could do but help conserve the patient's strength, make him comfortable . . . and hope for the best.

In fact, the doctor sadly signed death certificates for 33 out of every 100 pneumonia patients he treated. For those who survived, recovery was slow and expenses were high. The cost of an average case was about $1,000, including three or four weeks' time lost away from work.

Happily, this grim picture has changed. Under the onslaught of sulfa drugs . . . *and now the antibiotics* . . . pneumonia has steadily lost ground. Now, uncomplicated cases clear up in four to five days. And instead of losing 33 out of every 100 cases, the doctor saves all but a very few.

Just as striking as the cut in deaths and disability is the cut in the *cost* of *curing* pneumonia. More and more patients can now be cared for at home. As a result, the average case of pneumonia may cost no more than $100 . . . including loss of income, the doctor's visits and the "expensive" new medicines!

Today, more than ever before, an investment in prompt and proper medical care may well represent one of the biggest bargains of your life.

Copyright 1956—Parke, Davis & Company

PARKE, DAVIS & COMPANY
Research and Manufacturing Laboratories Detroit 32, Michigan

Makers of medicines since 1866

There are few subjects on which the general public is more uninformed (or perhaps *mis*informed) than the cost of modern medical care.

People have always grumbled about medical bills—and they probably always will, to some extent. The trouble is they tend to see medical expense as a part of sickness—something that certainly gives them no pleasure—rather than the price of enjoying good health.

But the real economics of the situation—what the patient gets for what he pays—proves that today's medical bill usually turns out to be one of the really big bargains of his life.

The latest Parke-Davis advertisement, reproduced here, cites the amazing decline in the cost of curing pneumonia to illustrate the remarkable value represented by your patient's investment in prompt and proper medical care.

This message will reach an audience of millions of readers in mass-circulation magazines such as LIFE and the SATURDAY EVENING POST. Reprints, in small folder form, are promptly available to physicians on request.

GENERAL

Authors

Manuscripts should be addressed to Arthur H. Wells, M.D., Editor, 915 East First Street, Duluth 5, Minnesota. Telephone RA 7-6636 or JA 5-2319. Original papers prepared for publication solely in Minnesota Medicine will be considered by the Board of Editors providing they fulfill the following editorial standards. Manuscripts should be typed double spaced on white paper with at least 1-inch margins. The original (not a carbon copy) is requested. The title on the first page should be under six words if possible or divided into two parts. The author should give his highest degree, his institutional position or his relationship to a hospital or medical organization which he may be addressing. Pages should be numbered consecutively and the author's last name should appear at the top of each page after the first page.

Biographical references should appear on a separate sheet entitled "Bibliography." They should appear and be numbered consecutively in the order in which they first occur in the text (not alphabetically). Citations in the text require reference numbers if the author's or authors' names are not used or if there is more than one reference to the same author or group of authors. All references to author should appear in the Bibliography and no references should be included which are not in the text. The style and exact punctuation used in the J.A.M.A. references is requested. For a journal this is: *Author's last name, initial, initial.: title of paper. Abbreviated name of journal, volume number: page, year.* Book references should give author, title, edition number, city, publisher and year.

Illustrations (photographs, tables and graphs) should be submitted separately and not combined in the text. There should be a separate sheet entitled "Illustrations" which contains the various types of illustrations listed separately and numbered in the order

New STEELINE Pediatric Table

Eases the burden of the physician's daily work

Includes built-in tare balance scale, built-in measuring rod, foam rubber cushion and electrical outlets with cord and plug—there are no accessories to buy. Top quality construction features include all-welded steel body, two roomy drawers and a large open compartment with shelf, providing easy, unhampered access to instruments and supplies. Front edge is protected from wear by a stainless steel baffle plate. Despite the fact that this new table has been designed to provide the physician with the best modern equipment, efficient modern production methods in our own factory permit us to keep the price well below that of comparable models. Write today for complete information.

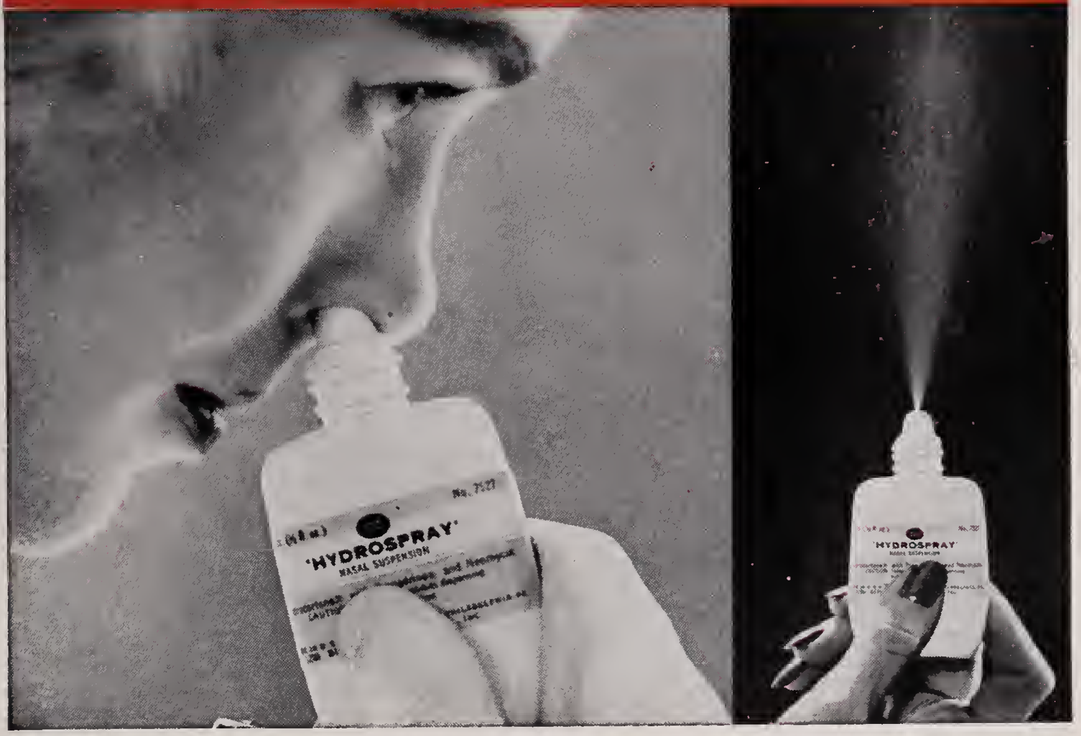
'Hydrospray' NASAL SUSPENSION

(HYDROCORTONE® WITH PROPADRINE® AND NEOMYCIN)

Anti-inflammatory—
Decongestant—Antibacterial

MAJOR ADVANTAGES: New synergistic anti-inflammatory, decongestant and antibacterial formula. High steroid content assures effective response.



Topically applied hydrocortisone[1] in therapeutic concentrations has been shown to afford a significant degree of subjective and objective improvement in a high percentage of patients suffering from various types of rhinitis. HYDROSPRAY provides HYDROCORTONE in a concentration of 0.1 % plus a safe but potent decongestant, PROPADRINE, and a wide-spectrum antibiotic, Neomycin, with low sensitization potential. This combination provides a three-fold attack on the physiologic and pathologic manifestations of nasal allergies which results in a degree of relief that is often greater and achieved faster than when any one of these agents is employed alone.

INDICATIONS: Acute and chronic rhinitis, vasomotor rhinitis, perennial rhinitis and polyposis.

SUPPLIED: In squeezable plastic spray bottles containing 15 cc. HYDROSPRAY, each cc. supplying 1 mg. of HYDROCORTONE, 15 mg. of PROPADRINE Hydrochloride and 5 mg. of Neomycin Sulfate (equivalent to 3.5 mg. of neomycin base).

New Study Shows Gelatine Restores Brittle Fingernails to Normal

KNOX
UNFLAVORED
32
GELATINE

Directions for making the Knox Gelatine drink in every package

Brittle, fragile or laminating fingernails are the bane of many a woman's existence. Yet this highly prevalent and distressing condition often has gone uncontrolled for lack of effective therapy. Now, you can promise these patients substantial relief in a large percentage of cases.

In a recent study[1] that confirmed previous work[2] Knox Gelatine was used to treat 36 women with fragile, brittle, laminating fingernails. The response was most gratifying. Except for three patients who discontinued the therapy, three diabetics, and two women who had congenital deformities, the splitting ceased and all other patients were able to manicure their nails to a full point by the time the study ended.

Optimal dosage proved to be one envelope (7 grams) of Knox Gelatine administered daily for three months. Improvement, however, was noted after the first month. If you would like more complete details of this work, just use the coupon.

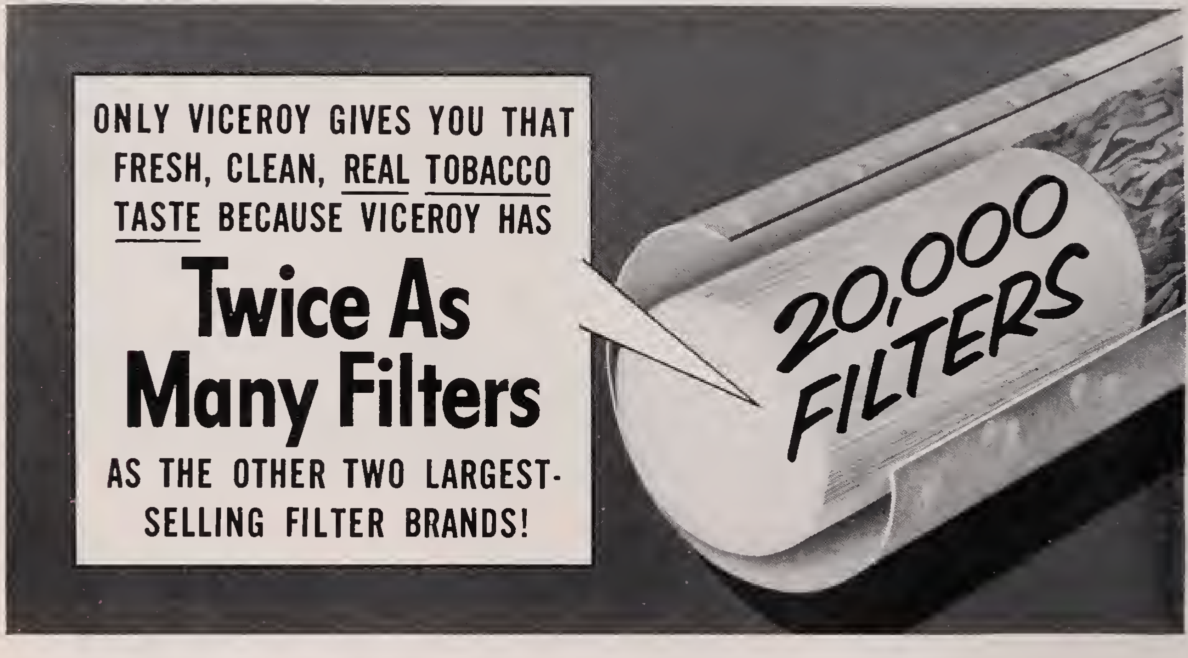
YOUR NAME AND ADDRESS

What makes Viceroy different from other filter cigarettes?



ONLY VICEROY GIVES YOU THAT FRESH, CLEAN, REAL TOBACCO TASTE BECAUSE VICEROY HAS

Twice As Many Filters

AS THE OTHER TWO LARGEST-SELLING FILTER BRANDS!

The VICEROY filter tip contains 20,000 tiny filters made exclusively from pure cellulose . . . soft, snow-white, natural. This is twice as many filters as the other two largest-selling filter brands. That is why VICEROY gives you such a fresh, clean taste—that real tobacco taste you miss in other filter brands. No wonder so many doctors now smoke and recommend King-Size VICEROYS.

If it's Viceroy you can tell the difference blindfolded!

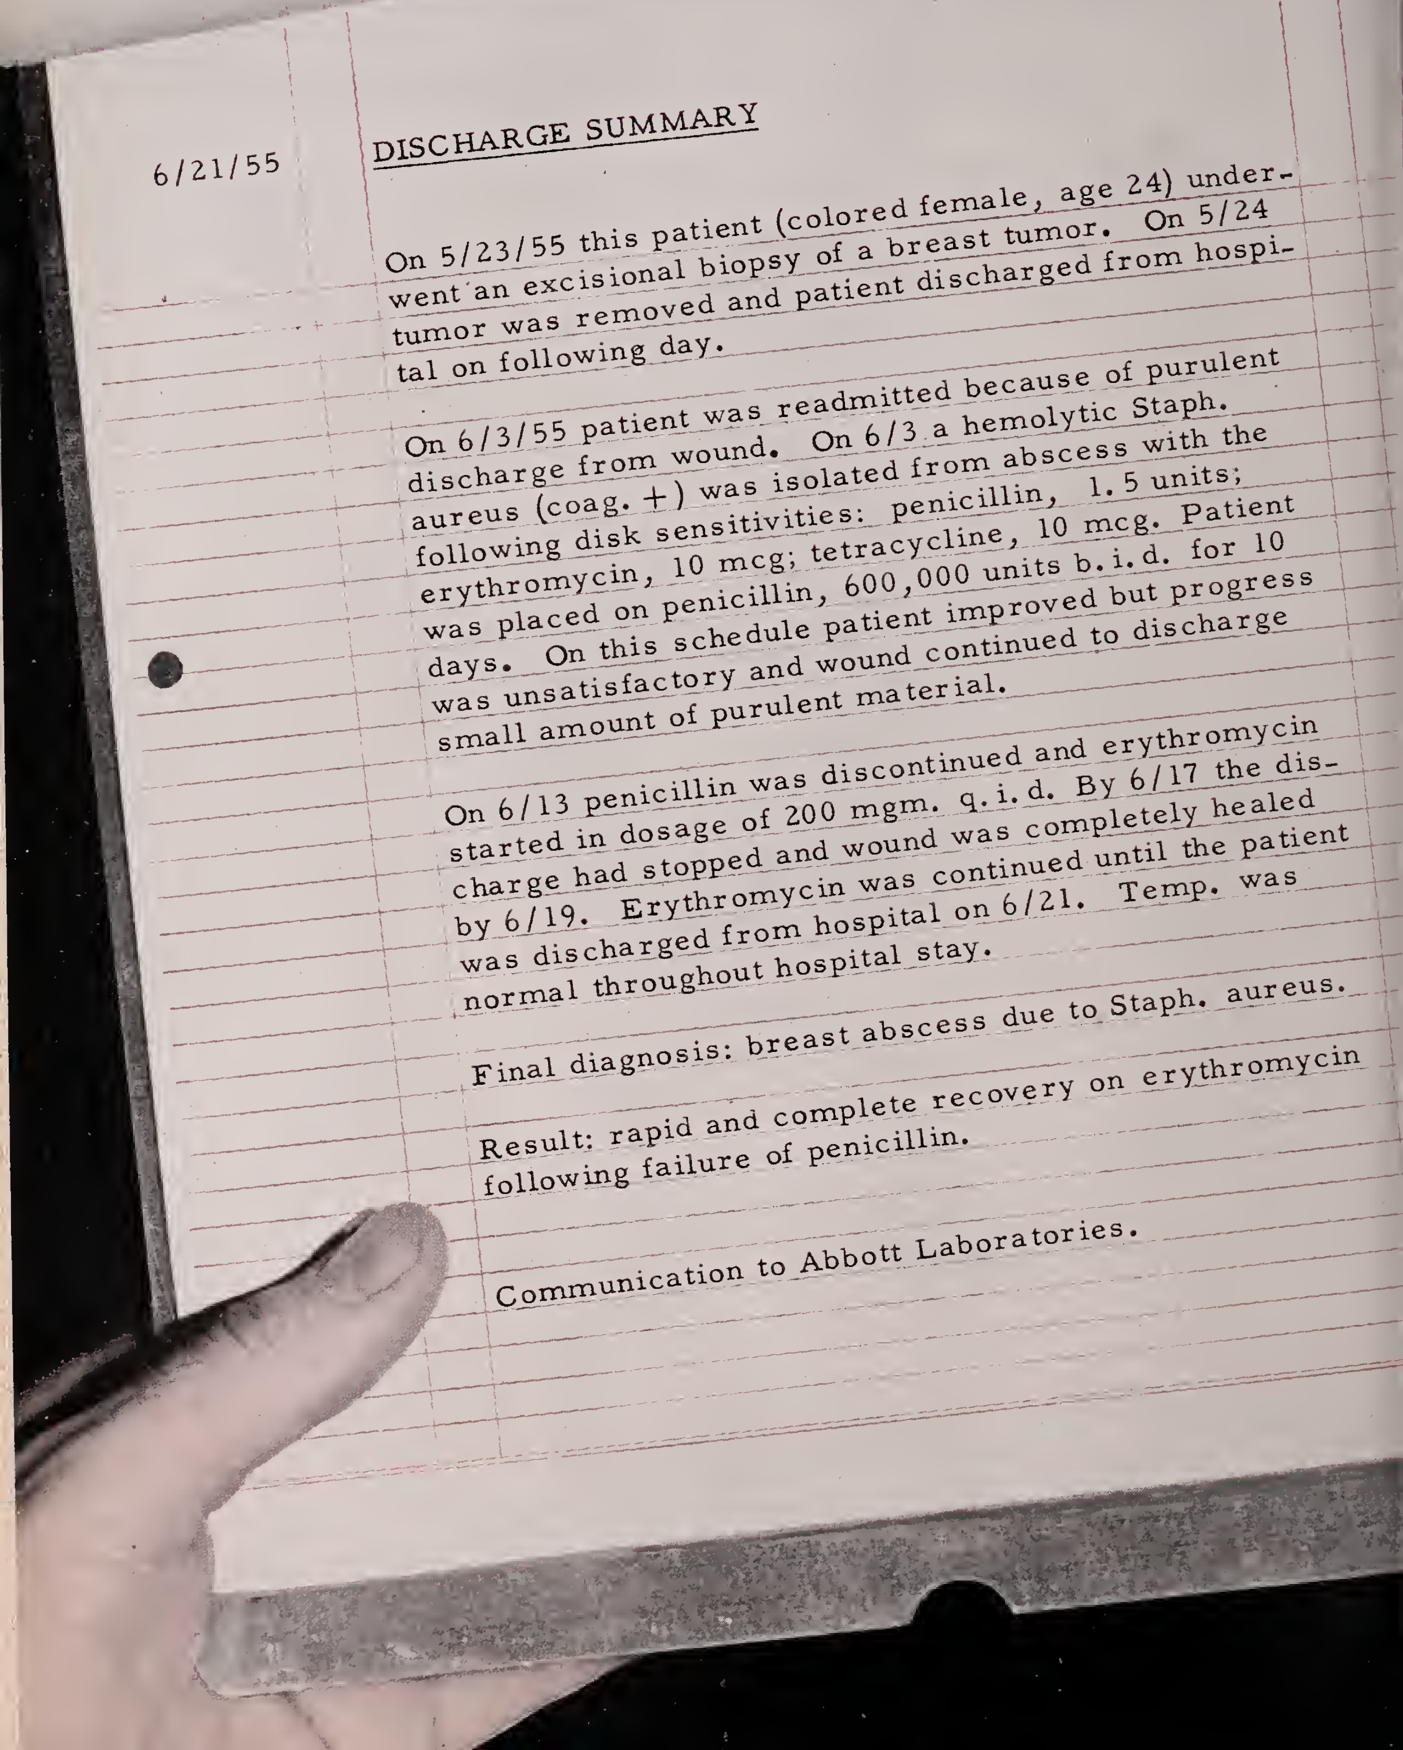
LOS ANGELES

Erythromycin in treatment of abscess



6/21/55

DISCHARGE SUMMARY

On 5/23/55 this patient (colored female, age 24) underwent an excisional biopsy of a breast tumor. On 5/24 tumor was removed and patient discharged from hospital on following day.

On 6/3/55 patient was readmitted because of purulent discharge from wound. On 6/3 a hemolytic Staph. aureus (coag. +) was isolated from abscess with the following disk sensitivities: penicillin, 1.5 units; erythromycin, 10 mcg; tetracycline, 10 mcg. Patient was placed on penicillin, 600,000 units b.i.d. for 10 days. On this schedule patient improved but progress was unsatisfactory and wound continued to discharge small amount of purulent material.

On 6/13 penicillin was discontinued and erythromycin started in dosage of 200 mgm. q.i.d. By 6/17 the discharge had stopped and wound was completely healed by 6/19. Erythromycin was continued until the patient was discharged from hospital on 6/21. Temp. was normal throughout hospital stay.

Final diagnosis: breast abscess due to Staph. aureus.

Result: rapid and complete recovery on erythromycin following failure of penicillin.

HydroCortone®
(HYDROCORTISONE, MERCK)

A valuable aid in rehabilitating the arthritic patient

MAJOR ADVANTAGES: Greater anti-rheumatic activity than cortisone; smaller doses produce clinical improvement faster and more uniformly.[1]

HYDROCORTONE is a practical long-term therapeutic measure in the majority of patients suffering from rheumatoid arthritis. The use of small doses of HYDROCORTONE in conjunction with conservative general measures will permit the safe management of these arthritics for prolonged periods of time. Such a program has been shown to provide moderate to great relief in a very high percentage of patients.[2] In severely handicapped people, HYDROCORTONE plus physical therapy will frequently allow the rehabilitation of arthritics who would not be helped appreciably by either measure alone.[3]

OTHER INDICATIONS: Still's Disease, rheumatoid spondylitis, psoriatic arthritis, traumatic arthritis, osteoarthritis, and bursitis.

SUPPLIED: ORAL—HYDROCORTONE Tablets: 20 mg., bottles of 25, 100, and 500 tablets; 10 mg., bottles of 50, 100, and 500 tablets; 5 mg., bottles of 50 tablets. **INTRASYNOVIAL**—Saline Suspension HYDROCORTONE-T.B.A.: 25 mg./cc., vials of 5 cc. Saline Suspension HYDROCORTONE Acetate: 25 mg./cc., vials of 5 cc.

'Merthiolate'

(THIMEROSAL, LILLY)

'Merthiolate' is highly active under virtually all conditions; is relatively nonirritating and nontoxic

'Merthiolate' is germicidal in dilutions up to 1:4,000 in serum media and is relatively nonirritating in the concentrations suggested for use. It also maintains its activity in the presence of soaps. The fact that 'Merthiolate' is used as a bacteriostatic agent in fluids for parenteral administration gives strong evidence of its safety.

Amebiasis

J. ARNOLD BARGEN, M.D.
Rochester, Minnesota

THE experience of physicians who have dealt with intestinal problems during the last thirty years suggests that amebiasis has been the first diagnosis in many cases of intestinal conditions in which diarrhea is a prominent symptom. No one should underestimate the importance of accurate diagnosis and adequate care of the patient who has a bona fide infection with Entamoeba histolytica, but it has been rather easy, in considering a patient who had diarrhea, to think of amebiasis, give the patient some antiamebic therapy, and then, if improvement did not come, go more thoroughly into the examination to reach a more definitive diagnosis. This approach to the problem has been rather too prevalent and it should be decried. Every effort should be made in any given case of diarrhea to make an accurate diagnosis before undertaking therapy, because there are so many different types of intestinal disorders associated with this symptom and the treatment varies with the nature of the condition.

Surveys by physicians in different parts of the country indicate that amebiasis occurs in 5 to 10 per cent of the people of the United States. Some have suggested an incidence of 20 per cent but this is probably far too high. At one time amebiasis was considered a disease of the tropics or at least a disease of warm climates where sanitation was not satisfactory. However, the disease has been found universal in its distribution over the globe. This has been known for many years by physicians everywhere, and no longer is it thought that amebiasis occurs much more frequently in southern regions of the United States than it does in Minnesota. Consciousness of its presence in the people who pass through the office of the everyday practitioner of medicine is the factor of greatest importance toward its recognition. Control of water supplies, proper food handling, and elimination of insects that are transmitters of the causative agent constitute important steps in the eradication of this serious disease. Too frequently the corner grocery store may be the distributor of amebae. With our modern methods of transportation, fresh vegetables can be shipped almost everywhere at all times of the year. It is important then that we make sure of the way these vegetables were fertilized and that they be carefully washed before eating.

Serious as amebiasis may be, it is nevertheless unfortunate when a patient who does not have amebiasis is treated for it on a trial basis. For instance, if a patient who has ulcerative colitis is given an unusual amount of arsenic in the form of carbarsone or treparsol as a result of an erroneous diagnosis of amebiasis, he may fail to respond later to other more satisfactory measures of therapy. How serious amebiasis or amebic dysentery can be will be illustrated by a case which I shall report later.

Of much greater importance, however, is the case in which the patient is found to be infected with E. histolytica and takes some form of treatment, which eradicates enough of the amebae so that none are found in the stools, only to have the symptoms recur in a few months. Equally important is the case in which there is complete eradication of the amebae, and then the patient goes back to living in the same environment in which he lived before, only to become reinfected. Adequate methods of therapy are available for amebiasis, and complete relief from it is not difficult. The important problem is that of reinfec-

tion. This is particularly so among our neighbors across the border. At the Mayo Clinic we see many patients from the southern part of our hemisphere, many of whom carry E. histolytica without the amebae causing any symptoms. These patients apparently have become immune to the action of this parasite, and so the parasite lives in happy commensalism with his host. However, such a person may leave the parasite in Minnesota or California or Florida, and someone not adjusted to its activities may become infected and suffer a violent illness.

Cases of amebiasis occurring in this manner, as a fulminating or acute illness, are relatively uncommon but they are of sufficient importance and frequency that the practitioner of medicine should be constantly on the lookout for them.

The chronic form of amebiasis is of much greater importance than the acute form. It causes ill health, lowered vitality and decreased resistance to other infections. Chronic amebiasis seldom impels a patient suffering from it to visit his physician; and thus, perhaps, the physician does not have in mind the possible presence of the disease. However, these patients can and do transmit the disease. The infection is frequently water-borne and is due to poor sanitation, but it is also commonly transmitted by food, food handlers and insects.

During the surveys in various parts of the country, members of the personnel of hospitals have been found to be infected with amebae. This is a not unusual occurrence, and it brings home the point that persons working in hospitals, in and around the kitchen in particular, should be carefully examined to be sure that they do not carry any transmissible disease.

Incidence

Someone has observed that amebiasis exists where people exist, and this is probably a reasonably true statement. Craig and Faust[1] have estimated that 20 per cent of the people of the United States have amebiasis; that would mean more than 30,000,000 persons. As a matter of fact, only about 5,000 cases a year are reported. However, the true prevalence of amebiasis, as opposed to the reported prevalence, may reach figures as high as 80 or 90 per cent in some regions. Although amebiasis is commoner and more severe in tropical and subtropical regions than in temperate regions, its frequency is less dependent on geographical distribution than on the level of sanitation in a given locality. Epidemics of amebiasis are unusual, but they can occur as a result of gross contamination; witness the epidemic in Chicago in 1933. Frazier,[2] working in an institution in Ohio in which the population is 3,000 persons of retarded mental development, found 800 cases of infection by E. histolytica but made the diagnosis 2,000 times; in other words, there probably were infection and reinfection.

The importance of the problem of sanitation and cleanliness in regard to infestation by amebae is well illustrated by the following facts: Many authorities had predicted a great increase in amebiasis after World War II, in which our boys fought in the Pacific. However, McHardy[3] has called attention to the fact that this anticipated increase has not materialized. This is as one would expect, for in the United States, where sanitation facilities are at their best, reinfection by amebae should not take place and once the amebae are eradicated, the former hosts should not have the parasite again. Unfortunately, this is not always the case. McHardy has estimated the incidence in the United States as about 3.9 per cent, gathering his data from reports of members of the American Gastroenterological Association, from the departments of parasitology of various medical schools and from other sources.

Diagnostic Considerations

It must always be remembered that amebiasis is transmitted from hand to mouth. Persons with unclean habits should not touch food which others are to eat. Human manure should never be used for the fertilization of vegetables; however, it is still being used in some places. In this way, improperly prepared vegetables may transmit the trophozoites and cysts.

The trophozoites may be destroyed by the gastric secretions, but from an epidemiologic standpoint the cysts of E. histolytica are much more important than the trophozoites. It has been found that a patient who has acute symptoms may pass an average of 15,000,000 cysts daily, and these cysts may remain viable for days. An "ameba carrier" is in reality a person who has amebiasis that has not manifested severe enough symptoms to necessitate the attendance of a physician. The seriousness of an epidemic of amebiasis is comparable to that of an outbreak of smallpox, yellow fever, bubonic plague or other similar acute conditions. However, although epidemics of the diseases just mentioned usually create a panic and result in prompt and drastic measures to clear up the infection, an epidemic of amebiasis frequently may be dealt with rather lightly and allowed to have its own way.

Most persons who are hosts to E. histolytica seem to have some symptoms that may be ascribed to its presence. Much has been said about the "carrier state" of amebiasis, but recent studies by physicians from various parts of the world indicate that this term has been used too freely, with the resulting tendency not to take the presence of E. histolytica in carriers seriously enough. Albright and Gordon[4] stated that there is no such thing as a healthy carrier of amebiasis. In an editorial published in 1947[5] it was stated, "The carrier represents an active stage of the disease." The evidence concerning the inability of the parasites to live in the lumen of the bowel without producing lesions is rather conclusive. The aim of specific treatment is the eradication of all the parasites from the host.

Diagnosis

Frazier has suggested classification of persons infected with amebae into five categories: (1) the group in which the host is entirely asymptomatic and simply a carrier of E. histolytica; (2) the group in which symptoms are local or systemic without diarrhea but in which gaseous dyspepsia, anorexia, fatigability and other symptoms are prominent and the patient has amebae in the stools; (3) the same as group 2 except that the patients also have periodic diarrhea; (4) the group with classic amebic dysentery; (5) the group with complications. From the standpoint of diagnosis, such a classification may be helpful, but from a standpoint of treatment, not so much can be said, because symptomatic or not, all persons infected with E. histolytica should be treated.

General physical examination may not reveal anything of significance. Certain complications, however, such as hepatic abscess or pulmonary infection, may direct attention to the source of the trouble. Digital investigation of the rectum usually does not offer diagnostic data except when the disease is advanced, and then the ulcers cannot be distinguished from those of tuberculosis. The stiff, diffusely narrowed, tubelike rectum characteristic of thrombo-ulcerative colitis is not found in cases of amebiasis. Moreover, the rectal wall tends to be soft and pliable, like that of the normal rectum.

The absolute diagnosis of amebiasis is dependent on the finding of E. histolytica in the feces or other bodily discharges. It is important to adopt a standard procedure for preparing the patient for these examinations. It is best to collect the specimen near the laboratory, and it is well to have toilet facilities at hand.

The patient should be advised to have a free bowel movement about twelve hours preceding collection of the stool to be examined, and if he does not have diarrhea he is directed to take from ½ to 1 ounce (about 15 to 30 gm.) of magnesium sulfate on the morning of the examination and then to eat his usual breakfast.

Oily preparations and oily food should be avoided for at least forty-eight hours before the patient takes the salts. It is well to have the entire stool for examination; if it is formed, material should be taken from several places; if it contains patches of blood, pus or mucus, samples of these should be examined. Material from several portions of loose stools also should be selected.

The typical stool when the disease is acute is often reddish brown, and it may contain dark-brown streaks of mucus. Here and there will be flecks of bloody mucus. Charcot-Leyden crystals are frequently present. The stools of patients who have amebiasis do not contain the quantities of pus seen in the stools of those who have thrombo-ulcerative colitis. Although they may contain more blood than pus, rarely are the massive bloody discharges that are encountered in severe thrombo-ulcerative colitis seen in amebiasis.

The stools should be examined immediately, or at least within thirty minutes after passage, for motile vegetative forms of the ameba and also for cysts. Preparations for microscopic examination may be made by emulsifying a small portion of the stool in a drop of isotonic saline solution placed on a clean glass slide, or a weak solution (1:1,000) of water-soluble eosin may be used instead of saline solution. A coverglass is placed over the material on the slide to be examined. The emulsion should be homogeneous and thin. Strong solution of iodine U. S. P. (Lugol's solution), run under the coverglass or used to emulsify the feces, is helpful. It will aid in the observation of the nucleus of the motile ameba, in counting nuclei in cysts and in identifying the masses of glycogen.

The examination should be made in a warm room, and a desk light shining on the stage of the microscope may be used. The amebae are refractive, and the light entering the field should be such as to allow them to stand out sharply.

It is a good plan, if amebiasis is strongly suspected and amebae are not found on the first and second examinations, to examine at least three loose stools on as many consecutive days. The formed stool can be emulsified with isotonic sodium chloride solution and centrifuged at a moderate rate, and the sediment can then be examined to advantage.

Other methods of examination of stools, such as by permanently stained preparations and cultures, are technically cumbersome and not in general use, although they give good results in the hands of expert parasitologists.

Complement-fixation tests have come into use in some large laboratories. Until recently, they have been more experimental and confirmatory than of real practical value to the average physician. In 1948[6] it was stated that the complement-fixation test was still considered unreliable, that the incidence of errors was still too great and that it was not a substitute for examination of the stool.

It is generally agreed now that the complement-fixation test as performed at the National Institutes of Health, the Army Medical Center or the Communicable Disease Center almost always gives positive results in the presence of amebic hepatitis or amebic abscess of the liver and is a useful adjunct in the diagnosis of these extracolonic lesions.

Proctoscopic examination is a valuable aid to diagnosis. About a third of the patients who have active amebic dysentery have demonstrable amebic proctitis, but only slightly more than a tenth of the patients who are infected with E. histolytica have grossly visible ulcers in the rectum. The proctoscopic appearance of the rectal lesions, even when repeated examinations of the stools give negative results, often provides sufficient evidence for a positive diagnosis. Even when E. histolytica cannot be demonstrated in the stool, it may be found in great numbers in the scrapings taken from the bases of the ulcers.

In the general run of cases, the ulcers are discrete and the mucosa between them, although not normal, is so mildly inflamed as to seem relatively uninvolved. In many cases of severe diarrhea resulting from E. histolytica, the rectal and sigmoidal mucosa appears normal or only slightly hyperemic on proctoscopic examination. However, when the ulcers appear, they are typically discrete and do not have any characteristics that might lead to confusion with any other type of rectal ulcer, except certain types of tuberculous ulcers and, occasionally, those associated with the presence of Balantidium coli. The ulcers of amebic dysentery, even in its earliest stage, are not very large or very numerous; the large ulcers, which, it is believed, result from secondary infection, are not to be considered as a part of the characteristic picture.

The amebic ulcer usually appears on the prominent folds of the intestinal wall or involves the valves of Houston. The margins are undermined by infiltration of the ulcerative process, and prominence of the ulcer is increased further by accumulation of material on the base, composed largely of numbers of E. histolytica. This accumulation projects above the margin of the ulcer; it presents a grayish-white covering over the center of the ulcer. This grayish-white cap is easily swabbed away, after which the true base of the ulcer is revealed right below the surface of the overhanging margins. This is the explanation of the punched-out or umbilicated appearance of the amebic ulcer. An amebic ulcer may be as small as 2 to 3 mm. in diameter, or it may be large and sloughing and measure 2 to 3 cm. in diameter, or even more, with irregular margins and overhanging, ragged edges; the latter type usually is seen fairly high in the colon. The usual ulcer is about 3 to 8 mm. in diameter, and there is generally a small zone of hyperemia surrounding it. In cases of acute amebiasis, in which the patient suffers from severe prostration and passes an excessive number of stools and in which sloughing and bleeding are present, it is difficult to identify any ulcer; the involvement is massive and diffuse, and a single ulcer is seen only occasionally in the sloughing, bleeding mucosa.

Roentgenologic examinations, after a barium sulfate enema, of patients who have amebiasis are important. Usually results are negative, and the examination thus helps rule out other intestinal lesions. In experience at the Mayo Clinic, patients who present positive roentgenologic evidence of amebic colitis are rare; when such signs are present, they are usually in the cecum and ascending colon. The positive evidence of amebiasis obtained on roentgenologic examination of the colon usually consists of a deformity that, in general, resembles that of other chronic ulcerative diseases. The differential diagnosis is based principally on the distribution of the involved segments. Thus, in the roentgenologic examinations of some patients, extensive involvement by destructive disease is noted in the cecum, the ascending colon and the rectum. The rest of the colon may be roentgenologically normal. In the North Temperate Zone, ulceration of the colon of amebic origin is likely to be less severe and less extensive than that which is of tuberculous or streptococcic origin. In a few instances, however, a deformity involving most or all of the large intestine has been observed, which under treatment has disappeared almost entirely. When the deformity has been extensive, the regular, smooth, narrowed colon characteristic of chronic ulcerative colitis is not present, but, rather an irregular deformity is shown. The impression given, even in extensive disease, is that involvement is more mucosal than mural.

Complications

It must always be kept in mind that the presence of E. histolytica in the intestine may be associated with distant metastatic lesions or abscesses of various kinds. These include particularly abscesses of the liver, lungs and brain, but pericarditis, pleuritis, splenic and urogenital abscesses and cutaneous ulcers have also been found. In addition to the abscesses of the liver, which are usually single and are situated in the right lobe, a condition described as "amebic hepatitis" is recognized. Thus, not infrequently, a systemic disorder may call attention to the presence of amebae in the intestine. Occasionally, the only evidence of systemic disease is an unexplained fever, which may go unrecognized for a long time until someone examines the stools of the person with the fever.

Amebic granulomas have occasionally been mistaken for carcinoma of the rectum. A cursory examination with the finger and even by protoscopy has made it impossible to differentiate these conditions in an occasional case. Whenever there is any doubt, material for examination for parasites should be taken. Much commoner than this, however, is amebic hepatitis or local amebic abscess. The latter usually occurs in the right lobe of the liver. How serious the condition can become is illustrated by the following case:

> A man, aged forty years, working for a meat-packing company in Minnesota, who had been a serviceman in the Pacific in World War II, had had periodic diarrhea for quite a long time. However, he did not wish to report the condition to his superiors because he was allowed time off only for brucellosis and a few other infections and not for diarrhea. So he went on. However, following his death his co-workers complained that he frequently, when they were cutting a carcass, had to run for the toilet and did this fifteen to twenty times a day, so that his work was quite inefficient. He was brought to the clinic in extremis, with marked emaciation, exhaustion and shock, and died within twelve hours. Necropsy revealed a huge hepatic abscess, this time in the left lobe of the liver, perforation into the pericardium, and pericarditis, perforation into the left pleural cavity and amebae in all the fluids.

How easy it would have been to prevent this patient's death if he had reported his condition in time! This is only one illustration of failure of individuals to recognize the serious warnings and signs of an impending severe amebic condition.

Treatment

The difficulties in the problem of treatment have been largely referable to and caused by failures in diagnosis. A well-established program of therapy scrupulously followed, with avoidance of reinfection, will control nearly all cases of amebiasis. Because diagnosis has presented difficulties and many cases have gone undiagnosed for a long time, many investigators have tried new forms of therapy, always thinking that some new and better form of treatment will surpass those used before.

The efforts of therapy divide themselves into three main groups. All of them represent forms of chemotherapy, designed to annihilate the amebae or prevent their causing damage. The first includes some of the newer antibiotics. Among these, one can list aureomycin, terramycin, chloramphenicol, neomycin, bacitracin and fumagillin. The second group of drugs includes the various arsenicals, and the third a variety of therapeutic agents, such as PAA-701 (diallyldiethylaminomethylphenol dihydrochloride).

The antibiotics are not true amebicides, for they do not destroy amebae in vitro. The dose of these substances is similar to that used for other conditions.

A number of physicians with considerable experience in the treatment of amebiasis have come to the conclusion that fumagillin is at the present time the most satisfactory of the antibiotics. McHardy and Frye[7] have been giving it in doses of 30 to 60 mg. daily for ten days. This would mean a dose of 10 to 20 mg. three times a day. They have come to the conclusion that combined therapy of one antibiotic with another may be more efficacious than any of the antibiotics alone. Anderson,[8] Black, Terry and Spicknall,[9] and Malewitz[10] have had similar experiences with fumagillin. Armstrong and associates[11] have found terramycin to be an excellent antibiotic in acute dysenteries, but with relapses they add other amebicides. Their report is based on the results of treatment in fifty-one cases.

The arsenicals and oxyquinoline continue in favor among those who have had considerable experience in the treatment of amebiasis. Levy and Talley[12] have advocated the use of mercaptoarsenal, 10 to 20 mg. per kilogram of body weight, a maximum of 1 gm. daily being given for five days. Tucker[13] has advocated the use of bismuth glycolylarsanilate (milibis), chloroquine phosphate (aralen phosphate), 500 mg. of the former three times a day, 125 mg. of the latter twice a day. Two such courses can be given. Sanchez Vegas[14] has also advocated the use of these two agents as the most effective amebicides. Ritchie and Yokogawa[15] treated with carbarsone and chiniofon 241 inhabitants of a single Japanese village, where it was said that 10 per cent of the people were infected with amebae. Among 106 re-examined five weeks later, there was only one recurrence, and seven months later, only four recurrences.

Other drugs, such as resotren, mentioned by Halawani, Abdallah, El Kordy and Saif,[16] and PAA-701, mantomide, mentioned by Dennis and Berberian,[17] have found favor recently.

When all this information is added up, one finds that the results do not surpass a suitable program in which carbarsone, emetine and diiodohydroxyquinoline (diodoquin) are used in proper amounts at properly spaced intervals. One of the important problems in the treatment of complications is the treatment of amebic abscess in hepatitis. Chloroquine phosphate has become one of the leading drugs in the control of this. A paper by Radke,[18] published in 1954, indicates that patients with localized abscesses frequently complain of sharply localized hepatic pain. In Radke's group of fifteen patients, twelve had this complaint. At this point the tenderness is at its maximum. There is a sharp extension to the back and at times to the clavicle. In six of Radke's cases the latter occurred. The diaphragm was elevated in ten cases. Treatment of these patients included the use of quinacrine hydrochloride (atabrine), 0.1 gm. four times a day for 30 days, combined for the first ten days with carbarsone, 0.25 gm. twice a day for small men and for women and three times a day for large men. If the liver is still enlarged or tender at the end of thirty days, give quinacrine hydrochloride until the condition is cleared up.

Chloroquine phosphate has been a most important drug in the recent therapy of these cases. Chloroquine phosphate is prescribed in tablets of 200 mg. each. A course of one such tablet three times a day for five days seems to be superior to emetine, as indicated by Bhattacharya,[19] who treated fourteen patients in this way with excellent results. Patel[20] treated eleven patients who had liver abscess, giving 0.5 gm. a day for ten or twelve days with good results.

Dwork,[21] in reviewing the problem of recent therapy on amebiasis, concluded that the drugs of choice at this time are fumagillin, terramycin, aureomycin, bismuth glycolylarsanilate (milibis), diiodohydroxyquinoline (diodoquin) and iodochlorhydroxyquin (vioform). I am sure there are many who would take exception to this list, but this is just an illustration of how various men have used various drugs in the treatment of this rather intractable condition and have advocated the use of various drugs in accordance with their personal experience. Since no one has had a very large experience with any single one, it cannot be said, "These are the drugs of choice. These should be used preferably to any others." And yet any program that includes the satisfactory and carefully planned combination of emetine, an arsenical and an iodide will probably give us as good as or better results than all the newer forms of therapy.

Many of the recent therapeutic suggestions will undoubtedly be found to have great value in the ultimate complete eradication of E. histolytica from human hosts. However, it can be said that, in the main, even today few diseases respond so well to treatment when it is properly given as does acute amebic dysentery. However, eradication of the parasites, prevention of recurrence and combating of the numerous irregular relapses have often been difficult therapeutic problems. The purpose of treatment is threefold: (1) destruction of amebae in the tissue, (2) destruction of amebae in the lumen of the intestine and (3) healing of the ulcerative lesions.

I have assumed that spontaneous cure of amebiasis does not take place and that the portal of entry of E. histolytica is through the large intestine. For acute dysentery the following combination of drugs has proved eminently satisfactory: emetine hydrochloride, carbarsone or phenarsone sulfoxylate (aldarsone) and diiodohydroxyquinoline (diodoquin) or one of the oxyquinoline drugs with a high iodine content. The emetine hydrochloride is given hypodermically, the amount and manner of administration varying somewhat with the severity of the disease.

For severe attacks of amebic colitis, my colleagues and I give 1 grain (about 0.065 gm.) of emetine hydrochloride every twelve hours until 6 grains (about 0.4 gm.) have been given. For the moderately severe attack, 2/3 grain (about 0.043 gm.), given twice a day until 4 grains (about 0.26 gm.) have been given, suffices. It may be well to repeat such a course after an interval of a week. A warning must be expressed about the use of emetine. Effective doses are likely to prove toxic; doses a little greater than therapeutic amounts have been found to injure cardiac muscle, and the effectiveness of emetine alone against amebae is not great. However, emetine is an excellent adjunct to other drugs for the relief of acute symptoms. In the doses mentioned, and with a total amount of the drug of not more than 10 to 12 grains (about 0.65 to 0.78 gm.) administered to any one person, we have not encountered symptoms of toxicity. Emetine is less toxic for the liver than are other recommended drugs, and it gives quick symptomatic control, thus preparing the way for more curative drugs.

At the same time as the doses of emetine are begun, a 0.25-gm. capsule of carbarsone or phenarsone sulfoxylate is given three times a day until twelve capsules (3 gm.) have been given. If administration of emetine is to be started on a given day, the patient should start taking the arsenical that morning before breakfast. Thus, he will begin to take the arsenical twelve hours before taking emetine, and he will take his last dose of the arsenical twelve hours after the last dose of emetine. After administration of carbarsone is stopped, 0.25 to 0.5 gm. of diiodohydroxyquinoline is given three times a day for seven days. Then the whole course, including the emetine and the arsenical, should be repeated. Only an occasional person is sensitive to arsenicals and may have a reaction in the form of dermatitis, fever and vomiting and occasionally diarrhea; very occasionally, visual and acoustic disturbances have occurred. If any of these symptoms occur, administration of the drug should be stopped promptly and one of the oxyquinoline derivatives should be substituted. It has been our experience that satisfactory results in the treatment of amebiasis will be achieved if this routine is followed. We have come to the conclusion that persistent, adequate and properly timed administration of these drugs is the keystone of successful treatment. The proper combination of these drugs, given in rather large amounts over short periods and yet in amounts which are unlikely to produce toxic effects, has resulted in cure of most patients with amebiasis. Thus it is seen that a suitable and successful course of treatment in the average case of amebiasis covers 22 days.

It is to be hoped that the addition of such antibiotics as aureomycin and the use of chloroquine phosphate in some of the cases in which abscess of the liver is suspected may be important steps in the final control of amebiasis.

Comment

The ultimate solution of the problem of amebiasis may be distant, but Craig's[22] statement, that in order to diagnose 90 per cent of the cases a technician or physician should spend two years under competent instruction and during that time examine thirty to forty stools a day, is probably a most authoritative suggestion and advice for those who are interested in this problem. It points up the experience of so many, that the examination of the stools for E. histolytica is the job of an expert, someone who has had considerable experience in the examination of stools and in distinguishing between this parasite, other parasites and epithelial cells which resemble some of these organisms. Then, too, if the doubt remains and the patient's symptoms point to amebiasis, a therapeutic test with some of these drugs may be justifiable.

Hormonal Treatment of Advanced Breast Cancer

E. A. REGNIER, M.D.
Minneapolis, Minnesota

THE subject matter of this paper concerns itself with a résumé of some clinical investigation which I have carried on in the past five years. I claim nothing new for the subject, but I believe its contents will reveal a new assessment of the value of the method and the results obtained. There is very little material in the recent literature on the subject and not much uniformity of opinion as to procedure and evaluation of results. Much needs to be done. Any form of treatment which is beneficial in the field of therapy in metastatic cancer of the breast deserves consideration.

The discovery by Beatson,[1] in 1896, that the ovary had a sustaining influence on breast cancer gave impetus to further study of this problem. He observed regression of two cases of cancer of the breast following oöphorectomy.

Lett[2] collected ninety-nine cases so treated and found marked improvement in 23 per cent and great benefit to another 15 per cent. This method of treatment fell into disfavor because of the added surgery and because of substitution of ovarian radiation, despite the fact that the latter method was slower and more uncertain in eliminating ovarian hormones.

Dr. Ira D. Nathanson[4] of Harvard University and his co-workers seem to have done the greatest amount of clinical investigation as regards the use of steroid hormones in the treatment of breast cancer.

The fact that castration alone has a beneficial effect on metastatic carcinoma of the breast and that estrogens and androgens likewise have beneficial effect seems rather paradoxical. Most authors agree, however, on the following points: In post-menopausal women, estrogens are superior to androgens in their objective favorable effect on the soft tissue manifestations of breast cancer. Contrariwise, androgens seem to yield a higher incidence of symptomatic relief with a relatively lower remission rate of the physical characteristics of the disease. The beneficial responses to androgens may occur in women of all ages but are usually more pronounced in the pre-menopausal era. As will be shown later, castration has an immediate beneficial effect on practically all cases of advanced breast cancer. In the pre-menopausal group, in fact up to the age of fifty-five, it is probably much safer to use just androgens because of the possibility of enhancing the growth of the carcinoma by treatment with estrogens. Most authors agree that after fifty to fifty-five years of age it is safe and probably best to use estrogen therapy. There is much evidence on the clinical results to show that estrogens and androgens exert their influences on breast cancer by somewhat different mechanisms. Androgens have a pronounced effect on bone metastases.

Nathanson noted that the pathological changes in the cancerous tissue after estrogen and androgen therapy resembled very much those following irradiation therapy. A gross observation of the primary tumor showed them to soften and some of the ulcerated areas to heal and the massive tumors to shrink very materially. He states that these same tissues showed microscopic changes similar to those seen after radiation therapy. He was also of the opinion that slow growing tumors seem to respond more satisfactorily to hormonal therapy. He further states that he was unable to determine from the histological studies whether the primary effect of steroids was on the cells or on the tumor bed. Tumors of low malignancy were the most responsive to various types of hormonal therapy. It is also generally agreed that hormonal therapy has both metabolic and hematological effects which are beneficial to the host.

This has been a difficult thing to explain because of the unknown methods of metabolizing steroids. Studies have been made on blood calcium and blood protein levels, on hemoglobin, red cell count readings and hematocrit readings, to-

---

Presented before the Minnesota Academy of Medicine, May 12, 1954.

gether with serum alkaline phosphotase tests, to learn more about steroid metabolism.

There is general agreement that the one common beneficial effect of treatment with hormones is the resulting sense of well-being. The uniformly elevated hemoglobins and rises in blood count suggest that the mechanism is either one of inhibiting the neoplastic cells in the bone marrow or it is one of stimulating the hematopoetic mechanism of the body directly. It is also known that hormones have a beneficial effect on protein metabolism in general. There is also the possibility that the major effects of estrogens are on the diseased cells directly, with secondary metabolic responses, and that the effect of androgens may be primarily metabolic in origin.

Nathanson[6] conjectures that the effect of androgens on protein formation may result from either stimulation of anabolism or the inhibition of catabolic processes and may be the deciding factor in the beneficial effect of this form of therapy. The fact that androgens are big factors in protein synthesis and osteogenesis must also be taken into consideration in interpretation of results. Tumor growth, therefore, may be handicapped by increased bone formation without direct effect on cancer cells. The mode of action therefore, of castration with use of estrogens and androgens is still very much unexplained. Nathanson states that it can be postulated under various circumstances that these three methods of treatment temporarily restore a substance that is hostile to the growth of cancer, or that these forms of therapy may help a natural defence reaction that in itself is not capable of reversing the course of the disease. In spite of the fact that there are so many unexplained answers in this method of therapy, it is encouraging to know that the tumor may be diverted from its anticipated course by essentially physiological processes stimulated by this form of therapy.

One can deduce that hormonal therapy is designed to alter the chemical environment of carcinoma cells dependent of hormones for their well-being. Sisson and Garland[7] mentioned that surgical castration or irradiation castration will bring about remission of metastatic lesions of bone and soft tissues in 20 to 25 per cent of the cases. Most authors feel that the percentage is closer to 50 per cent. Most authors agree that androgens should be used in treating patients under fifty-five years of age and estrogens used in the older group. Most people suffering from advanced breast carcinoma will respond to either androgens or estrogens and some people not doing well on one will improve on the other. Some authors alternate in the therapy, using both of these chemical drugs. Various doses have been suggested. The subcommittee of steroids and cancer therapy suggests doses of 150 mg. of testosterone weekly for a period of twelve weeks, minimal doses of estrogen to be 4 gm. and minimum length of treatment to be six months. Most authors agree that survival time of the patients treated for advanced cancer of the breast is increased after hormonal therapy. This is unproven statistically. The clinical course of the disease is more favorable.

Higgins and Dale[3] also suggests that the furtherance of this improvement, if hormonal therapy *per se* is not adequate, should be enhanced by adrenalectomy. This phase of therapy is not to be taken up at this discussion, however. Many authors feel that the use of hormone therapy should not be instituted until the patient has had failure from other methods of therapy, namely, radical surgery plus irradiation. The cases reported in this series are all cases having had surgery, some radical and some palliative plus irradiation of some form or other. The report of the council on pharmacy and chemistry in the *Journal of the American Medical Association* (June, 1951) gives the following results: The mean survival time of the patients treated with palliative irradiation was twelve months; with testosterone propionate, 7 5/10ths months; with estrogens, 7 6/10ths months to 13 3/10ths months. They conclude that some cancers are composed of cells of sufficient functional maturity that their activity and growth are retarded by removing the source of hormones supplying them. They also are of the opinion that immature cancers do not respond favorably to withdrawal of steroid hormones.

The twenty cases that I am reporting are chosen from some forty cases who had some form of hormone therapy, but only those cases which were well controlled and could be followed have been chosen. Some of them have not been under treatment long enough to warrant reporting on definite results. Therefore the twenty cases reported here are those that have been followed from one to five years and all of which have had adequate followup studies. As I stated before, these patients all had some type of operation, some of which was radical surgery and some of which was only palliative plus irradiation. This form of therapy was followed by hormone therapy as soon as evidence of recurrence of tumor in any portion of the body was evident. Length of treatment varied from six months to four years.

At the beginning of treatment we were more conservative in the dosages of medication given because of the inadequate information on what was the optimum dosage to be used. There is still no uniform opinion as to what constitutes an adequate dose, although the consensus seems to be that the 100 mg. of testosterone twice a week for a period of four to six months should be adequate and that a varied dose of estrogens from 15 mg. a day to 40 to 50 mg. a day for a period of six months should be adequate for estrogen therapy. During the past two years we have had to modify this dosage greatly because of our clinical observations. It has been evident from observing our patients that when 200 mg. per week were adequate for some people, this dose had to be doubled and tripled for others. It has also been our observation that a patient not doing well on this specified dose may improve greatly upon doubling the amount. This has been especially well demonstrated by some of the cases which are described below.

We have not selected cases for hormone therapy. All patients with metastatic carcinoma received either testosterone propionate or stilbestrol. We have used testosterone on patients under fifty years of age. They were all cases that had had x-ray studies of their bones and chest to determine whether or not they had metastases to the chest or to the osseous tissues. Serum calciums were studied on a few of these people but not universally done because we found no cases in which there were marked alterations in serum calciums under therapy. We evaluated the results of the treatment by noting regression of soft tissue lesions, regeneration of osseous lesions, relief of pain and evidences of improvement in general well-being such as weight gain, improved appetite, improved states of blood depletion and clearing of pleural effusion. Unfortunately we have also had the experience of seeing in one or two cases no regression whatsoever of the disease or possibly augmentation of the disease. The complications of therapy have been very few. True, there has been an occasional case of hirsutism, an occasional case of acne and some disturbances of the libido. This has not been marked or disturbing. Stilbesterol has been the drug of choice for estrogen therapy. We have had no cases of increased or severe uterine bleeding in the use of estrogens. One must also be cognizant of the possibility of electrolyte disturbances in these patients under intensive therapy.

Case Reports

Case 1.—This patient, Mrs. R., presented herself with a tumor of her right breast at age of thirty-eight. The tumor was biopsied and found to be malignant, and she had a radical breast operation November 30, 1946. The carcinoma was described by the pathologist as well differentiated adenocarcinoma, grade II, with negative axillary nodes. Her progress was very uneventful until June, 1950, when she began to develop abdominal distress. Within ten days of this time she developed some abdominal ascites and small nodules in her pelvis. Dr. Lang saw her in consultation at this time. At operation on June 7, 1950, an inoperable carcinoma of the ovary was found with generalized metastases covering the entire surface of the liver and peritoneum. At this time she was given deep x-ray therapy to the four pelvic fields. She received a total of 7,800 r of deep therapy to the pelvic fields. During all this period the patient had been absolutely free of any evidence of recurrence of the breast carcinoma, except for a small lesion which developed in the left breast which was about ½ cm. in diameter and very firm and very freely movable.

Because of the increasing abdominal fluid it was necessary to do abdominal paracentesis July 10, 1950, and August 5, 1950, where 6 to 8 quarts of fluid were removed from the abdominal cavity each time. Notes on her chart repeatedly recorded a small tumor in the left breast which remained unchanged. Because of the persistent ascites, it was necessary to again repeat the course of x-ray in June, 1951, where 8,700 r of radiation were given to the four pelvic fields. The patient's condition remained good. She was able to do her housework, and carry on through all this difficulty. On June 26, 1951, x-rays of her chest revealed a slight amount of pleural effusion on the left; 100 mg. of testosterone were given twice a week intramuscularly. This was the first evidence of metastatic carcinoma on her breast. This is rather significant insofar as she had survived a carcinoma of the ovary with generalized metastases throughout her abdomen. This should be most inimical to the inhibition of growth of a breast carcinoma because of the ovarian secretions. However, the ovaries had a tremendous amount of radiation and this may have kept the secretions in abeyance.

X-rays taken July 28, 1951, showed more fluid in the left chest than on previous examination; and the ribs, the sixth and the ninth on the left, and the eighth and ninth on the right, were now invaded by carcinomas. On September 1, 1951, the left pleural effusion showed marked increase and the rib lesions remained about stationary. One month later, x-rays of the ribs showed slight amount of healing, the patient having been on testosterone therapy ever since June of this same

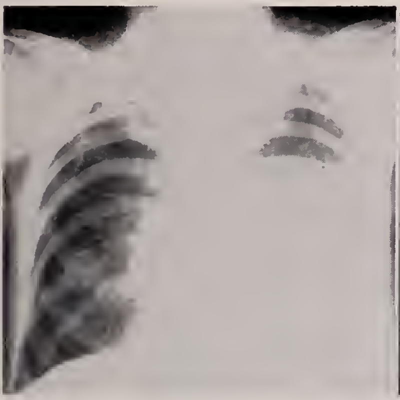

Fig. 1.

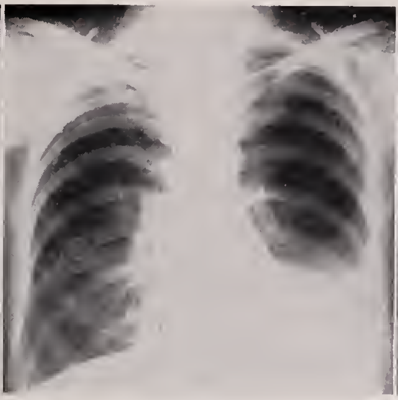

Fig. 2.

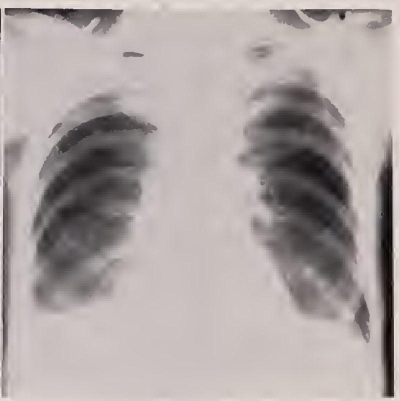

Fig. 3.

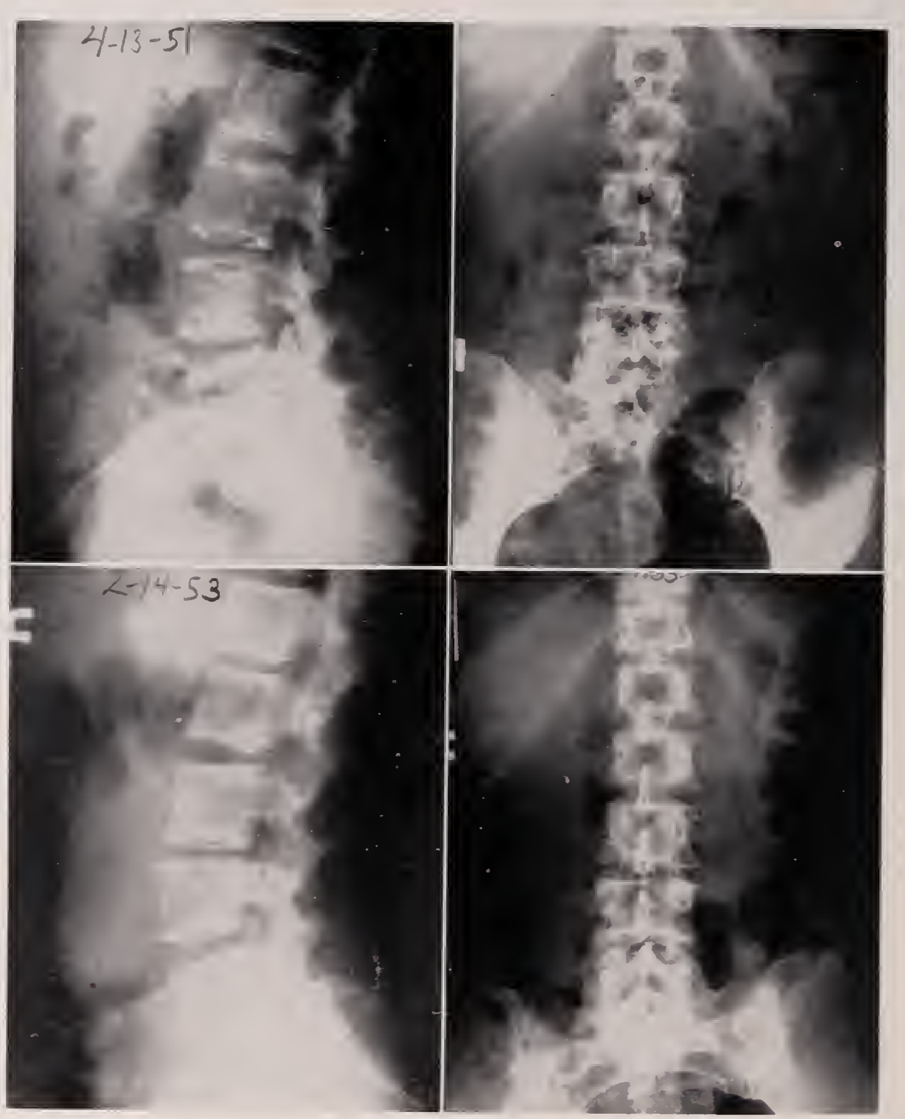
year, which meant that she had been on testosterone therapy for three months. At this time the fluid in the left chest remained about the same. On November 5 there appeared to be less fluid in the chest and the ribs showed some evidence of healing. Further x-rays taken January 12, 1952, showed some involvement of the glenoid fossa on the left and still evidence of metastases in the various ribs described above. Although there was now a slight pleural effusion at the right base with evidence of thickening of the right pleura, there was less effusion in the left base. X-rays of February 9, 1952, showed the bony lesions were now healing and both lung bases were beginning to clear. On April 5, 1952, the pleural cavities were clear, the lung fields were clear, the pleural thickening seemed to be decreased, there was no evidence of carcinomatous metastases in the chest at this time, and the bones showed more healing. On May 31, 1952, the lung fields were clear, the bony processes were stable, and the patient was absolutely comfortable, maintaining her weight, doing all her work but having ascites.

About this time the patient began rapidly accumulating ascites, but the pelvic examination revealed no increased evidence of carcinomatosis. However, in July she began to fail and the gastrointestinal studies showed that she had a high degree of intestinal obstruction at this time. This became more pronounced so that later she had to have an exploratory operation because of a complete bowel obstruction. This revealed involvement of all abdominal viscera in a carcinomatous covering which had matted all the viscera in a ball-like mass in the upper abdomen. The patient died a week later of the intestinal obstruction. It was impossible to relieve the obstruction surgically.

This case illustrates, I believe, in a classical manner the beneficial effects of androgen therapy in a relatively young woman who survived a carcinoma of the breast with surgery and no irradiation to the breast itself. She was given androgen therapy as soon as metastases developed and was able to carry on with most of her regular duties despite an intervening carcinoma of the ovary which ultimately caused her death. From November, 1946, until June, 1951, no demonstrable evidence of recurrence of breast carcinoma could be demonstrated except for the tumor of the left breast. However, she survived the breast carcinoma by approximately seven years; she survived the metastatic lesions of the breast carcinoma by thirteen months under androgen therapy, and she survived the combination of the two carcinomas, one by seven years and the other by over two years.

The evidence manifested by the films (Figs. 1, 2 and 3), I believe, speaks very strongly in favor of the fact that the only factors that sustained this woman throughout her metastases of breast carcinoma were the androgens she was taking. The fact that they show bony healing and the progressive healing of the chest lesions and the progressive disappearance of the effusion in both sides of the chest, I believe, is revealing. One can only conjecture what her expectancy might have been had she not suffered from the carcinoma of the ovary. X-rays show bony healing and regression of all chest fluid.

Case 2.—The second case that was indicative of the beneficial effect of androgen therapy was that of Mrs. H. This woman had a biopsy of a breast tumor done in Florida in 1948, when a simple mastectomy was done. In October, 1949, she presented herself with metastatic lesions in the axilla. A complete radical operation was then done, removing pectoral muscles and all the nodes in the axilla. This was diagnosed as adenocarcinoma, grade III, metastatic. This woman was put on testosterone therapy and was maintained on this therapy both by injections and by mouth in the form of linguets, a total dose of 30 mg. a day, and she was maintained in comfort on this form of therapy until April, 1951, when she developed a rather severe pain in her back and was brought to the hospital. At this time x-rays revealed that she had profound bony metastases of her ribs, spine and pelvis. The pain was so severe at this time that she was given a few x-ray treatments, simply to relieve her pain, and the doses of androgens were intensified to where she was getting 400 mg. a week for a while. This was cut down to 200 mg. a week, and she was maintained on intensive doses like this for a period of two years. In spite of the heavy doses, she had only slight voice changes and a slight amount of hirsutism but otherwise was free of symptoms. She remained well until September, 1953, when she became very ill and was hospitalized and a diagnosis of coronary thrombosis was made. A very short time after coming in to the hospital she died. An autopsy showed no evidence of active carcinomatosis anywhere in her body. The only demonstrable cancer consisted of four or five small nodules in the liver which were umbilicated and stationary.



Figs. 4. 5, 6 and 7.

From the appearance of x-rays taken at these two-year intervals (Figs. 4, 5, 6 and 7), I believe that the amount of bony healing shown, and the fact that she was free of symptoms, maintained her body weight, maintained her blood in good condition and carried on her regular duties in life until she was struck with the coronary thrombosis, is ample proof of the efficaciousness of this form of therapy. The films show changes under hormone therapy.

Case 3.—The third illustrative case is that of Mrs. M. J., age 58, a patient seen at the clinic at the General Hospital. This patient presented herself with a cystic tumor in the left breast. She was operated upon on October 29, 1948. The first time a simple mastectomy was done; a 5 cm. cyst, nonmalignant was reported. The patient remained well until December, 1950, when she noticed induration around the scar in the region of the operation of the left breast and some enlargement of the nodes in the left supraclavicular region. She went back to the hospital where a biopsy was done, and these lesions showed a scirrhous carcinoma. A 3 by 4 cm. mass was present in the right breast, with retraction of the right nipple and an orange-peel type of skin reaction. Chest x-rays at this time were negative. Laboratory work was all normal, and the patient was well otherwise except that she showed a hypertension of 200/100.

In July. 1951, that patient was given 15 mg. of stilbesterol three times a day. This was continued for four months when it was discontinued for a short time. During this interval the mass in the right breast showed a very definite shrinkage and nodules disappeared promptly over the left chest wall. She was seen by Dr. Stenstrom at the University, who advised against any x-ray therapy.

On July 30, 1951, x-rays were taken of her spine and these were normal. In August, 1951, she was again given stilbesterol, 35 mg. daily and was kept on this dosage for one month when the stilbesterol was increased to 40 mg. daily. While on the 40 mg. dosage, this patient's soft tissue lesions improved markedly. She felt well until February, 1952, and the nodule in the right breast remained smaller and stationary. Nodules began again to appear on the left chest wall. In June, 1952, it was noted that there were nodules in the right axillary space. This patient remained on 40 mg. of stilbesterol daily until November, 1952. At this time the nodules in the right breast and the right axilla were decreasing markedly in size. X-rays taken in August, 1952, showed the thoracic spine and lumbar spine to be involved with carcinomatous metastases. In January, 1953, the lungs and ribs showed questionable involvement by carcinoma. In April, 1953, there were carcinomatous nodules appearing in the lungs, ribs and the entire spine was involved. In September, 1953, x-rays showed more involvement of the ribs and across the clavicles. There was fluid in the right pleural cavity and there was further evidence of pulmonary metastases. In February, 1953, two nodules again appeared in the left chest wall. Notes made in April, 1953, showed that she was still on the same dosage of stilbesterol. The right breast and axillary nodes and skin lesions remained status quo and there were some supraclavicular nodes involved on the right. In August, 1953, this lady was put on 150 mg. of stilbesterol daily. Serum-calcium at this time was 9 mg. Serum phosphorus was 3 mg. In October, 1953, she began developing some fluid in the right chest. This was increasing slightly. Therefore the medication was changed to 200 mg. testosterone every two weeks. Serum calcium at this time had risen to 12.2 mg. On December 22 a note was made that the patient was markedly improved and generally felt better. In January, 1954, all the carcinomatous nodules were again regressing. In view of the improvement under testosterone therapy, in other words, in shifting from estrogens to androgens, it was decided to give this patient the minimum of 200 mg. a week, and she has been on this dose ever since that time and has continued to show marked improvement. The films (Figs. 8 and 9) show regression of chest fluid.

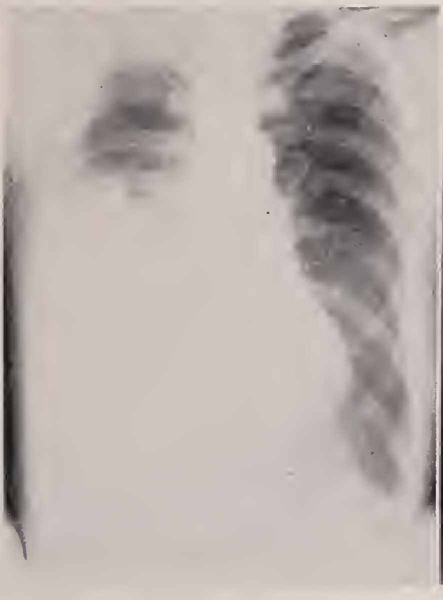


Fig. 8.

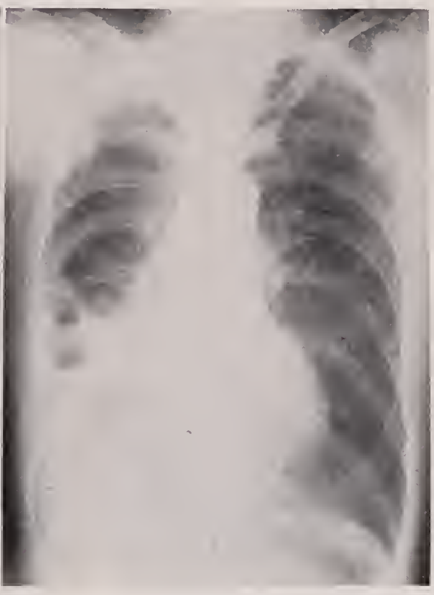

Fig. 9.

Conclusions

Any therapeutic procedure must prove its value to the patient. Uncomplicated procedures such as irradiation of ovaries plus the use of androgens and estrogens can be instituted by any physician.

I believe the evidence presented here justifies the conclusion that these measures are rational, safe, beneficial to the patient and prolong life in some cases beyond usual expectancy after generalized metastases have occurred (Table I).

These patients practically all improved subjectively though not always objectively. There is evidence here that cancer cells do not have the autonomous properties ascribed to them but are dependent on hormones for their growth.

We have positive evidence that the course of breast cancer may be retarded by the administration of sex hormones.

Further observation on the effect of hormones on breast cancer should help clarify their mode of action and help us solve the mode of cancer

TABLE I

Time elapsed from surgery to metastases:	Time elapsed from onset of metastases to death:
Average for group: 4 yrs. 4 mos.	Average: 19.6 mos.
Longest interval: 9 yrs.	Longest interval: 4 yrs.
Shortest interval: 1½ yrs.	Shortest interval: 6 mos.

growth. A new form of therapy may provide a new approach to the study of cancer.

The response of breast cancer to hormonal therapy suggests that physiologic mechanisms for the control of cancer may be present in the body. A way of releasing this mechanism or stimulating it must be found.

There is ample evidence in the response to treatment of the cases cited above to justify the use of much larger doses of both estrogens and androgens than have previously been recommended.

Blood chemical studies and electrolyte balance must always be checked at first evidence of disturbance.

Problems in the Clinical Diagnosis and Classification of Ventricular Hypertrophy in Adults

II. Right Ventricular Hypertrophy

BEN SOMMERS, M.D.
Saint Paul, Minnesota

THE SECOND in this series of three papers dealing with diagnostic cardiac problems is devoted to a case of isolated right ventricular hypertrophy.

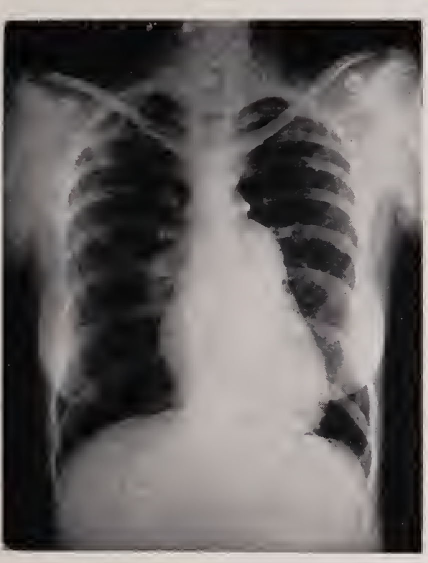

Fig. 1. Roentgenogram demonstrating right ventricular enlargement and prominence of the shadow of the pulmonary trunk.

Report of Case

A thirty-three-year-old white woman was seen in January, 1944, complaining of dyspnea and exertional pain in the thorax and arm. She had two children, aged three and one-half years, and one year. Both childbirths had been uneventful. Slight shortness of breath at night had begun when she returned home from the hospital after the birth of her younger child, and shortness of breath on exertion and angina had begun six months later. Hoarseness had been noted three months previously with a sinus infection but had persisted after the infection had disappeared. A thoracic roentgenogram taken in 1941 revealed no abnormalities, and the cardiac silhouette was normal.

Examination disclosed no cyanosis or clubbing of the fingers or toes. The only abnormalities found consisted of a soft systolic murmur along the left sternal border that was poorly transmitted and heard best in the fourth interspace, a snappy pulmonary second sound reduplicated on exercise, x-ray evidence of moderate right ventricular enlargement with a prominent shadow of the pulmonary trunk (Fig. 1) and electrocardiographic evidence of right ventricular strain (Fig. 2). The blood pressure was 108/78. The sedimentation rate was 61 mm. in one hour (Westergren). Results of the Kline test were negative.

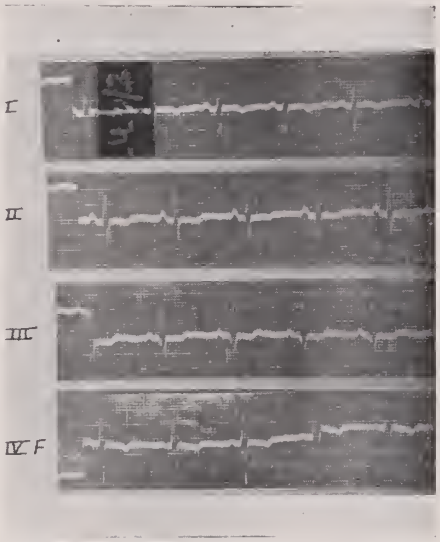

Fig. 2. Electrocardiographic evidence of right ventricular strain.

Dr. George Fahr saw this patient in February, 1944, and concurred in the diagnosis of an interventricular septal defect.

On supportive therapy, including digitalis, the patient was fairly comfortable until March, 1944, when pericarditis developed, with a septic temperature, a loud dry friction rub, thoracic pain and a sedimentation rate

Part II of thesis submitted for admission to the Minnesota Academy of Medicine, April, 1954.

of 73 mm. She was hospitalized because of a suspicion of subacute bacterial endocarditis but repeated blood cultures remained sterile and splenomegaly and petechiae did not develop. Antibiotics were not given. At dismissal in June, 1944, the sedimentation rate was still elevated (43 mm.), but the pain and fever had abated. However, electrocardiographic studies revealed progressive right ventricular strain.

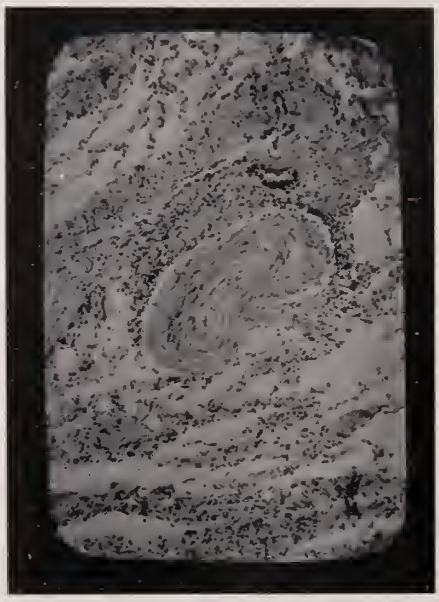

Fig. 3. Low-power magnification of section of lung, showing fibrous intimal thickening of a large muscular artery.

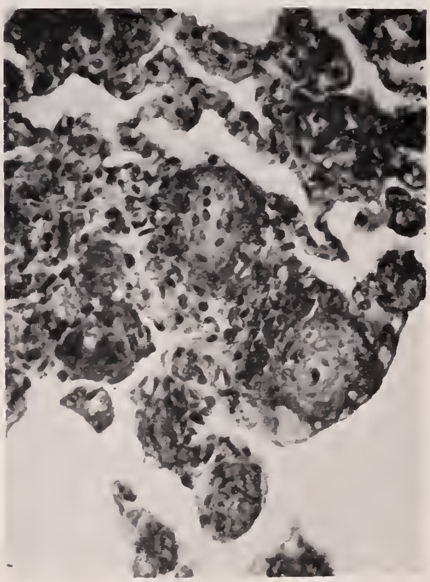

Fig. 5. High-power magnification. Fibrous intimal occlusion of small muscular arteries of lung (Verhoeff's stain).

In July, 1944, a pericardial friction rub, accompanied by fever and thoracic pain, recurred for two days. In early August, progressively severe right heart failure developed, with abdominal distention, hepatomegaly and edema in the sacral region. A blood culture at this time was sterile. Death occurred in August, 1944, approximately nineteen months after onset of symptoms.

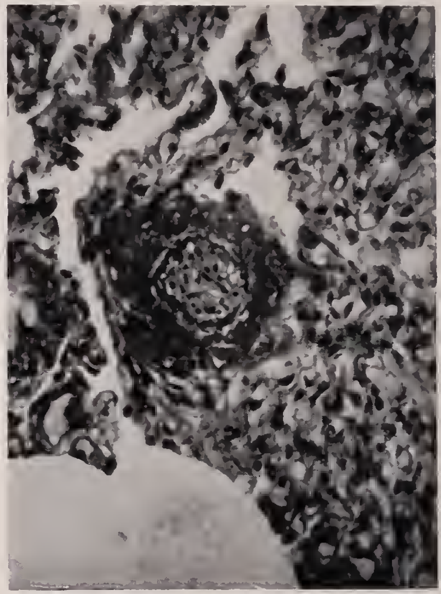

Fig. 4. High-power magnification of section of lung showing medial hypertrophy of a large muscular artery (Verhoeff's stain).

Necropsy was done by Dr. Kano Ikeda. The pericardial sac contained 60 cc. of clear, serous fluid. The heart weighed 400 gms. A few fibrous adhesions were present at the root of the pulmonary artery; otherwise the epicardium was smooth. The myocardial color was not remarkable. The left ventricle was slightly hypertrophied. The right ventricle and auricle were enormously hypertrophied and dilated. The myocardium was fairly firm. The mural endocardium was smooth, and the valves showed no disease. The root of the aorta presented a smooth intimal surface. The coronary arteries were patent and appeared normal.

Grossly, the lungs appeared normal except for slight atelectasis in the dependent portions. The bronchi, pulmonary veins and pulmonary arteries were normal. There was chronic passive congestion of the liver and kidneys.

Microscopic sections of the myocardium were not remarkable. Microscopic sections of the lungs were considered to be within normal limits at that time, showing very minimal sclerotic changes in the smaller bronchial arteries.

Comment

On restudy of this case in 1953 and 1954, these sections were sent to Dr. Jesse E. Edwards, at the Mayo Clinic, for his opinion. At his request, elastic-tissue stains were made. His report follows:

> "Two processes exist. One is characterized by medial hypertrophy of the large muscular arteries; the other process consists of fibrous narrowing or occlusion of vessels in the arteriolar and small muscular arterial classes. The latter change, that is, the fibrous intimal thickening, at times has a honeycombed effect resembling organized thrombus. There is, in addition, occasional fibrous intimal thickening of the large muscular arteries. Also, there is an occasional elastic artery showing lipoid deposition in its intima associated with a fibrous proliferation, a picture to be classed as atherosclerosis."

The histologic findings are pictured in Figures 3, 4 and 5.

In 1944, cardiac catheterization had not been performed in Minnesota. The vascular changes in the lungs in this case were, however, similar to those seen in patients whose pulmonary-artery pressures have been measured and found to be elevated during life. This type of case has been called by some "primary pulmonary hypertension" and by others "pulmonary hypertension resulting from occlusion of pulmonary vessels by thrombi or emboli." Consideration of the etiology of this type of disease is beyond the scope of this paper, but the reader is referred to papers by Brenner[1] and by Dresdale and co-workers.[2] The extensive pathologic and clinical investigations of Edwards and his associates[3-11] have failed to convince him that pulmonary hypertension occurs as a primary condition.

This case, although clinically a problem as to the cause of the right ventricular hypertrophy, may now be considered an example of right ventricular hypertrophy associated with pulmonary hypertension. It is well to emphasize that, before right ventricular hypertrophy is considered idiopathic, various categories of disease known to be associated with right ventricular hypertrophy must be ruled out by necropsy. These conditions, according to Edwards,[10] include (1) impaired pulmonary venous flow, (2) disproportion between pulmonary blood flow and the capacity of the pulmonary bed and (3) common ventricular ejectile force for both the systemic and the lesser circulations in the absence of pulmonary stenosis. Edwards listed twenty-two separate conditions under these three categories, with many subdivisions. Unfortunately, many of these conditions are easily overlooked at necropsy.

Of special interest in this case was the apparent minority of pulmonary arteries involved. The small amount of tissue removed for sections may be part of the difficulty, a better method of study probably being injection of the pulmonary arteries with radiopaque material similar to the Schlesinger technique for studies of the coronary arteries.

The pathologic diagnosis of thrombotic or embolic pulmonary vascular disease in this case is well supported by the clinical history and course. Symptoms began immediately after a pregnancy and were preceded by a normal chest film two years earlier. Still unexplained, however, were the two attacks of pericarditis and their substantiation, however scanty the evidence, at necropsy.

In 1946, Castleman and Bland[12] described organized emboli of the tertiary pulmonary arteries as an unusual cause of cor pulmonale. A forty-four-year-old housewife survived for nine years with cor pulmonale after pregnancies at thirty-one, thirty-three and thirty-five years of age and a pelvic operation at twenty-nine. Pelvic thrombi during pregnancies or following the pelvic operation were believed to be the source of her emboli.

Muirhead and associates[13] reported another case following pregnancy and one associated with cryoglobulinemia. Similar cases associated with pregnancy or with transfusion of blood contaminated by cotton fibers and by other foreign bodies, and the experimental production of pulmonary sclerosis in rabbits by means of intravenously administered human fibrinous blood clots, Lycopodium spores, amniotic fluid and autogenous blood clots, attest to the interest shown in this condition of late years.

In reviewing the literature on idiopathic right ventricular hypertrophy[14-19] and earlier publications on pulmonary arteriosclerosis[20-23] one cannot help wondering whether one or more of the afore-mentioned conditions listed by Edwards was not overlooked in many of these recorded cases. The three cases of Dresdale and associates[2] classified as primary pulmonary hypertension, and encountered in a two-year period in a 500-bed general hospital were all in women who were twenty-five, thirty-five and thirty-three years of age. The second case, the only one in which necropsy was done, showed pulmonary sclerosis in both small and larger branches, with thrombi. Thrombo-embolism associated with pregnancy might have been the causative factor in one or more of these cases, as well as in the three young women reported on by East.[14] Amniotic-fluid embolism has been reported in several cases but this substance acts as a foreign body and may be removed with passage of time, leaving thrombi in various stages of canalization.

Summary and Conclusions

A case of right ventricular hypertrophy, considered to be idiopathic after clinical and necropsy study but shown by more recent pathologic investigation to be due to thromboembolic pulmonary vascular disease associated with pregnancy, has been reported. A brief review of this subject is included, with a brief outline of the subject of primary and secondary pulmonary hypertension.

Until the numerous causes of pulmonary hypertension have been ruled out, some of which are easily overlooked, it is perhaps well to remain skeptical of the existence of primary pulmonary hypertension. Meanwhile, the antemortem diagnosis of this condition does not seem justified.

CARDIAC OPTIMISM

Instilling a hopeful outlook is the most important thing a physician can do to assist a victim of coronary thrombosis to return to normal life. And such optimism is fully justified for most heart patients, according to Dr. Paul Douglas White of Boston, noted cardiologist recently called into consultation on President Eisenhower. Even in cases of severe heart damage requiring long convalescence, "the resumption of work is usually possible, although the occupation may need to be changed if it is too strenuous." And with the pace of present research, "there may be something just around the corner that may prove helpful to some who at present seem hopelessly ill.

"Thought of this possibility may actually aid in prolonging the life of some patients sufficiently to take advantage of new discoveries when they come," for "idleness breeds unhappiness and is actually bad for the health. It is a rare patient who is fit for nothing."—P. D. White: Medigrams, *GP*, 12:89 (Dec.) 1955.

The Use of Blood and Plasma Expanders during the Third Trimester of Pregnancy

THOMAS H. SELDON, M.D.
Rochester, Minnesota

IN the event of a major obstetric emergency, necessitating vigorous supportive therapy during the third trimester of pregnancy, the intravenous administration of a blood-volume expander, blood plasma or whole blood may be a lifesaving measure. Two examples of such emergencies are those caused by placenta previa and abruptio placentae. Both of these emergencies may result in considerable loss of blood with possibly a marked deleterious effect on the well-being of the mother, as well as the expected baby. Not infrequently, everyone practicing obstetrics may be faced with such an emergency with severe loss of blood and, at the same time, be unable to move the patient to a hospital before supportive treatment must be instituted.

The importance of whole-blood transfusion in the treatment of shock accompanying these two conditions goes without question. There is no substitute for hemoglobin and erythrocytes. The use of plasma-volume expanders is of real value at times, but it never was intended to supplant the transfusion of whole blood. However, the usefulness of plasma-volume expanders results from the low cost of manufacture, the ease of storage for long periods, and their effectiveness in emergency treatment of loss of blood volume and shock. Most of these products can be transported easily and may be administered in homes, ambulances or the emergency admitting ward of a hospital.

Of all the plasma-volume expanders currently available, dextran, polyvinylpyrrolidone and gelatin appear to meet most of the criteria required of an acceptable product. The ideal one has not been discovered.

The plasma-volume expanders appear to be of greatest use when the loss of blood does not exceed 20 per cent of the total blood volume. When more than 35 per cent of the total blood volume has been lost, the anemia commands attention. Therefore, transfusions of whole blood, with or without the use of plasma-volume expanders, are indicated.

Dextran

Solutions of dextran in this country are available under various trade names. The chemical nature and the molecular form, size and shape of the dextrans have been studied. Use of a 6 per cent solution has been effective in restoring blood volume and in improving blood pressure. Pulaski[1] stated that after injection of dextran tagged with C^{14} into the dog, the urine shows 65 to 70 per cent of the radioactivity, with 4 to 6 per cent in the expired carbon dioxide and 3 to 5 per cent in the viscera at the end of seventy-four hours. About 25 per cent cannot be found. Material marked with C^{14} also was found in the liver, spleen and lymph nodes.

Part of the retained dextran is metabolized. Michie and Ragni[2] found no clear evidence of renal damage, although depression of tubular function has been noted.

Polyvinylpyrrolidone

Polyvinylpyrrolidone (PVP) is a synthetic macromolecular polymer first produced in Germany early in World War II. The raw materials used in its production are ammonia, acetylene and formaldehyde. In a concentration of 3.5 per cent in isotonic solution of sodium chloride, with a molecular weight of 40,000, this substance has a desirable colloidal osmotic pressure and viscosity. There is no evidence that this product is metabolized. Forty per cent appears in the urine in the first twenty-four hours. At the end of seventy-two hours, 28 per cent is still unaccounted for, as far as excretion in the blood or the urine is con-

cerned. In the mouse this product is stored in the endothelial cells of blood vessels, the reticuloendothelial cells, the liver and the kidney.

Gelatin

Solutions of gelatin have been used for several years. A 6 per cent solution has about the same osmotic pressure as is exerted by plasma. Particles of a molecular weight of less than 30,000 are excreted in the urine. Four hours after infusion of a 5 per cent solution of gelatin, Jacobson and Smyth[3] found that 70 per cent was still retained in the blood. Fifty per cent of the particles of a molecular weight of more than 30,000 to 35,000 are reported to be retained for twenty-four hours. This product has been used satisfactorily for treatment of patients suffering from shock. Changes in tissue produced by gelatin consist of transient swelling of the tubular epithelium of the kidney and temporary storage in the liver and reticuloendothelial system.

The use and value of whole-blood transfusion in some conditions will be referred to later in this presentation.

Emergency Measures

During the delivery of the baby, emergencies requiring supportive therapy may arise from severe bleeding, from lacerations, from postpartum atony and from retained secundines. An unusual happening, postpartum inversion of the uterus, may result in severe shock, necessitating the emergency administration of plasma-volume expanders or of whole blood.

An emergency transfusion of blood may be started with cross-matched compatible blood, using low-titer group O Rh-negative blood, if the patient is in the hospital and if his group is unknown and if sufficient time is not available for determining the group and Rh type of his blood.

In so far as possible, it is advisable to administer cross-matched blood of the same group and Rh classification as that of the patient, instead of un-cross-matched group O Rh-negative donor blood. However, if the emergency demands speedy administration of blood, low-titer group O Rh-negative donor blood may be used.

In the institution with which I am associated, blood is collected in 500-cc. vacuum bottles containing anticoagulant acid citrate dextrose solution. Disposable sets for intravenous administration are used. Fifteen-gauge or 18-gauge needles are introduced into accessible veins. Infiltration with a local anesthetic at the site of venipuncture makes the procedure more comfortable for the patient.

The rapid administration of a large quantity of whole blood sometimes is necessary. One of the commercial distributors has an administration set made of one of the plastic materials which can be used for forceful introduction of blood into the patient's veins. Another technique used not infrequently is to introduce air into the vacuum bottle and create within the bottle a positive pressure that is sufficiently high to force the donor blood into the patient's venous circulation.

It is very desirable for all physicians to be aware of the fundamental principles of this subject of emergency blood transfusion. For this procedure to be carried out satisfactorily, it is important for the physician to be able to introduce needles into veins without discomfort or trauma to the patient. Too frequently, interns, residents and others have had little or no instruction in the technique of venipuncture. It behooves all of us to teach interns and residents all the many tricks that go to make a successful venipuncture. This instruction is invaluable when emergencies arise that necessitate the intravenous introduction of fluids or whole blood for needed supportive therapy.

Why Not Pack the Postpartum Uterus?

JACK R. PIERCE, M.D.
Virginia, Minnesota
EDWARD G. WINKLER, M.D.
Buffalo, New York

THIS paper is devoted to a consideration of hemorrhage from the postpartum uterus due to atony. Bleeding due to lacerations or retained secundines are not considered, unless atony was also part of the clinical picture.

Recently, statements have been made by some rather prominent obstetricians to the effect that they did not believe in packing a postpartum uterus, or that they never had packed, or that they never would. In one instance, the obstetrician making this statement was also reporting several hysterectomies done post partum because of uterine atony.

There have been very few statements by the proponents of packing. Many good obstetricians pack the atonic, bleeding uterus. We feel that it is a good procedure. To us, it is inconceivable that hysterectomy should be done for postpartum atonic bleeding, without first having properly packed the uterus.

Some statistics are presented in Table I which support our contention that packing is a good procedure. These statistics were collected from the Edward J. Meyer Memorial Hospital and the Buffalo Hospital of Sisters of Charity, Buffalo, New York, and from the Virginia Municipal Hospital, Virginia, Minnesota. They cover all deliveries in the past six years in the first two hospitals mentioned, and all deliveries in the past twelve years in the last mentioned hospital. These are consecutive deliveries. No cases have been deleted for any reason. During the periods mentioned, there were 38,403 deliveries in these institutions; 505 cases had postpartum packing of the uterus because of atonic bleeding. There was one hysterectomy for postpartum atony. In this case, the uterus was not packed. The patient was under the care of a physician who apparently did not subscribe to the procedure of packing. There was no mortality due to postpartum atonic hemorrhage in this series. There were no serious complications in the patients who were packed. Besides the intrauterine pack, we also use the prescribed methods of uterine massage, intravenous Pitocin, ergonovine and blood transfusions. We may have employed the pack somewhat more often than absolutely necessary. Since none of these women died of postpartum hemorrhage or lost her uterus, we feel that this is not a serious fault.

TABLE I. POSTPARTUM ATONIC BLEEDING IN 38,403 DELIVERIES

Hospital	Deliveries	Packed for Bleeding	Hysterectomies-Atonic Bleeding	Mortality
Edward J. Meyer Memorial	6,309	179	0	0
Sisters of Charity	22,618	310	0	0
Virginia Municipal Hospital	9,476	16	1*	0
Total	38,403	505	1	0

*This patient was not packed, by the physician's choice. Actually, no hysterectomies were performed among those patients packed.

The physiology of postpartum uterine atony is not well understood. There are several questions which must be answered by any physiological explanations of atony. (1) Why does a uterus which has gone through a normal first, second and third stage of labor suddenly become atonic in the fourth stage? (2) Why does a uterus which has gone through an abnormal, inertia-type of first, second and third stage of labor have a normal fourth stage?

Certain terminology should be understood before considering atony. By *contraction,* we mean the act of muscle shortening. By *retraction,* we refer to the relaxation phase between contractions. During this relaxation phase, however, the muscle does not return completely to its original length. Eastman[1] states that retraction is the ability of a muscular viscus to contract down on its decreasing contents with the tension remaining constant.

Where does postpartum bleeding come from? Usually, it is from the large sinuses at the site of

---

Presented at a meeting of the Minnesota Obstetrical and Gynecological Society, April 30, 1955.

the placental implantation. How is postpartum bleeding normally controlled? Contractions of the various muscle fibers, by compressing and twisting the sinuses, staunch the flow of blood temporarily during the contraction. If retraction is adequate, even in the relaxation phase between contractions, there is enough compression and kinking of the sinuses to prevent a heavy flow. Finally, thrombosis and fibrosis control the bleeding permanently. It follows that in order to retract, the muscle must first contract. A uterus which can do neither, probably must come out. We have not seen such a uterus.

People who do not use packs have given many reasons for their ineffectiveness: packs prevent contraction; prevent retraction; cause infection; and merely soak up blood. In answer to these objections, we can state that our packs, when removed, are practically never blood-soaked; they are wet with a serous pink fluid. We have had no serious morbidity. Basic physiology teaches that increasing the tension in a hollow viscus increases the contractibility of the viscus. Reynolds, Kaiser and Harris[2] state that the contractibility and retractibility of the uterus are dependent upon the radius of curvature of each individual muscle fiber and the amount of intrauterine tension.

We believe that a uterus which is contracting and retracting enough to cause delivery of a fetus and placenta does not suddenly, totally, lose the ability to contract and retract. The delivery of fetus and placenta decreases the intrauterine tension and decreases the radii of curvature of the muscle fibers. This may remove enough of the stimulus to cause a partial loss of the contractibility and retractibility. We believe that a properly applied pack, by increasing uterine tension and the radii of curvature of the muscle fibers, increases the ability of the uterus to contract and retract, thereby controlling bleeding.

Usually, when a pack is unsuccessful, it is because it has not been properly applied. Since the gradient of contractile force is from the fundus towards the cervix, it is at the fundus that the intrauterine tension and radii of curvature must be first increased. This can be easily accomplished by one man, using a cannister-type packer* (Fig. 1) devised by one of us (E.G.W.), with a roll of sterile 4-inch gauze. The tip of the packer is inserted through the cervix to the fundus. It should be palpated through the abdomen to note that it is in correct position before packing is begun. By successive, rapid strokes of the toothed plunger, 5 to 10 yards of gauze packing can be inserted within a few seconds. Additional sterile gauze packs may be placed in the packer and tied to the preceding roll, if more packing is necessary. Increasing the gauze in the fundus backs the packer out of the uterus as it becomes full. It should be noted that no retractors are necessary and that the gauze does not touch any part of the patient before being deposited in the uterine cavity. The pack need not remain in long. Some of ours have been removed after as short a time as thirty minutes. Others have remained in twenty-four hours. Actually, as soon as the uterus begins to contract normally on the pack, it can be slowly withdrawn, removing a few feet at a time so that the uterus is not suddenly, emptied.

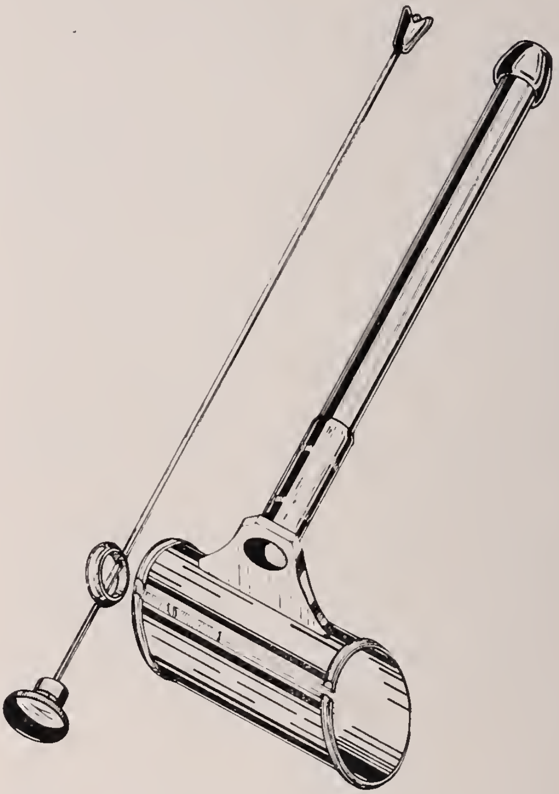

Fig. 1. The cannister type (Gomco) uterine packer used in this study. A 4 inch gauze may be inserted into the cannister and the free end brought up through the slot and into the barrel. It may be sterilized already loaded. Additional sterile 4 inch gauze rolls may be inserted as needed while the packer is in use.

CLINICAL REVIEWS

Mayo Clinic and Mayo Foundation

April 9, 10 and 11, 1956

Rochester, Minnesota

This 3-day program will be devoted to lectures and discussions on problems of current interest in general medicine and surgery. The presentations will be made by staff members of the Mayo Clinic and the Mayo Foundation for Medical Education and Research.

The number of physicians who can be accommodated is necessarily limited. Those wishing to attend should communicate with Mr. R. C. Roesler, Mayo Clinic, Rochester, Minnesota.

There are no fees of any kind.

Oxygen Therapy in the Premature Infant as a Cause of Retrolental Fibroplasia

ROBERT W. HOLLENHORST, M.D.
Rochester, Minnesota

LITTLE doubt remains that the injudicious administration of oxygen to premature infants is a major factor in the development of the retinopathy of prematurity, or retrolental fibroplasia.

This tragic disease, in which the retinal vessels and their supporting connective tissue proliferate onto the surface of the retina and into the vitreous, is the major cause of blindness in the United States today. Of all infants affected by retrolental fibroplasia, 98 per cent are premature, predominantly those whose birth weight is less than 1,500 gm. About 2 per cent of cases are found in full-term infants.

The first signs of the disease usually appear during the first month of life. The retinal vessels enlarge and become tortuous. Hemorrhage or transudation may appear and neovascularization may be present. The active stage may develop slowly or with extreme rapidity. Activity usually subsides during the third or fourth month and the cicatricial phase begins about the sixth month.

Course of Retrolental Fibroplasia

At the 1954 meeting of the American Academy of Ophthalmology and Otolaryngology, a panel on the subject of retrolental fibroplasia[1] recommended division of the course of the disease into three periods, namely active, regressive and cicatricial.

Active Period. — The panel subdivided the period of activity into the following five stages: (1) the vascular stage, in which the retinal vessels become dilated and tortuous and in which regions of neovascularization may appear in the periphery; (2) the retinal stage, in which the vitreous becomes hazy, neovascularization becomes more advanced and hemorrhage and gray edematous zones may appear in the peripheral parts of the retina; (3) the stage of early proliferation, in which newly formed vessels invade the vitreous; (4) the stage of moderate proliferation which is arbitrarily reached when such proliferation involves half the retina and (5) the stage of advanced proliferation, which is reached when the entire retina becomes detached or massive intraocular hemorrhage is present.

Regressive Period. — Regression occurs commonly. In about a third of the infants who have retrolental fibroplasia, the disease does not progress beyond the aforementioned Stage 1; the disease stops at Stage 2 in a fourth of the patients, while the disease in the remainder goes on to Stages 3, 4 or 5. When the disease is mild, the patients recover with little permanent damage. The disease occasionally may regress for a period and then briefly become active again if an infection develops.

Cicatricial Period. — The cicatricial phase follows the period of regression. The amount of permanent damage varies from none to a completely disorganized mass of detached retina, hemorrhage and proliferated vessels. The panel also divided this period into five stages as follows: (1) minor changes, consisting of a slight change in vascular caliber, small zones of retinal pigmentation or small masses of opaque tissue in the periphery of the fundus; myopia is common in these patients; (2) distortion of the optic disk, which may be caused by contraction of scar tissue in the peripheral zones; the disk and blood vessels are drawn toward a peripheral mass; (3) a retinal fold, which may extend to a mass of opaque tissue, usually in the temporal periphery, and as a rule contains the retinal vessels; several such folds may be present; (4) an incomplete retrolental mass, which may cover part of the pupillary region, and (5) a complete retrolental mass, which

---

Part of a round-table discussion at the meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, May 23 to 25, 1955.

From the Section of Ophthalmology, Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

is composed of detached retina and fibrous tissue and which may completely fill the retrolental space; elongated ciliary processes are visible at the equator of the lens; the anterior chamber may be extremely shallow but later it may become extremely deep; anterior and posterior synechiae are common; secondary glaucoma and an opaque cornea occur; because growth of the eye is inhibited, the eye remains small and the upper lids appear sunken.

The disease in about a fourth of the afflicted infants develops to Stages 4 and 5 of this cicatricial phase; in a third of the patients, it develops to Stages 1, 2 or 3, whereas the disease in the remainder heals with no visible residuals.

Pathogenesis of Retrolental Fibroplasia

Vascularization of the retinas of animals and human beings occurs relatively late in embryonal life. Vascularization in man is essentially complete at full term, whereas in mice, rats, kittens and puppies, this process continues for a variable time after birth. As a consequence, the premature infant is born with an incomplete retinal vasculature. Retinal vascular proliferation normally is most active during the sixth and seventh months of embryonal life; retrolental fibroplasia is most likely to develop in babies born at this period.

Retinal vascular proliferation progresses normally in the unborn child under conditions of low oxygen tension. If this condition persists into extra-uterine life and oxygen deficiency is absent at this time, no difficulties ensue. However, if a high oxygen tension is produced by exposure of the infant to high concentrations of oxygen, the retinal vessels constrict greatly. If this tension is maintained for three or four days, an irreversible vasoconstriction may obliterate these vessels as the result of either adhesions of the vascular endothelium or intravascular clotting, according to Ashton and associates.[2,3] Thus, hypoxia ensues and vascular proliferation begins. Instead of a smooth growth, the capillaries now sprout to form whorls of varicose capillaries like renal glomeruli. The supporting mesenchymal connective tissue also proliferates. Hemorrhage and transudation may appear, and the capillaries burst out of the retina to form sheets on the surface of the retina and in the vitreous. Retinal detachment is caused by both transudation of fluid and fibrotic strands in the vitreous.

TABLE I. INCIDENCE OF RETROLENTAL FIBROPLASIA IN PREMATURE INFANTS WEIGHING LESS THAN 1,500 GM.

Year	Infants	Retrolental Fibroplasia, Cases
1948	4	0
1949	4	0
1950	3	0
1951	14	3
1952	4	1*
1953	6	1
1954	5	1
Total	40	6

*Also one case in a 1,720-gm. infant.

Relationship to Oxygen Therapy

Typical lesions of retrolental fibroplasia have been produced by exposing newborn puppies, rats, mice and kittens to high oxygen tensions.

Szewczyk[4] presented evidence that the disease appears as a result of hypoxia induced either at or before birth, followed by further injury by means of relative hypoxia when the infant is removed too rapidly from an atmosphere containing high concentrations of oxygen.

The personnel of eighteen hospitals collaborated in a study of large groups of premature infants whose birth weights were less than 1,500 gm. This study was reported by Kinsey and Hemphill.[5] These infants at birth were assigned to one of two groups, namely (1) a "routine oxygen group" who received oxygen for twenty-eight days at a concentration of 50 per cent or more and (2) a "curtailed oxygen group" who received oxygen only on the basis of frank chemical need. The mortality rates were the same in each group. However, retrolental fibroplasia developed in 73 per cent of the first group and only 30 per cent of the second group; 25 per cent of the first group but only 6 per cent of the second group had permanent ocular damage. The initial ten days of exposure to oxygen appeared to be the most damaging. Those patients exposed to a concentration of oxygen of less than 40 per cent had a lower incidence of the disease.

During the period 1948 through 1954 at St. Marys Hospital in Rochester, Minnesota, there were 10,826 live births, of which 689 represented prematures weighing 2,500 gm. or less. Of this group, forty surviving infants weighed less than 1,500 gm. Retrolental fibroplasia developed in six (15 per cent) of this group and in one infant who weighed 1,720 gm. These babies were distributed as indicated in the table. All patients at this hospital are under the care of Mayo Clinic physicians.

Just why cases of this disease were not encountered at the Mayo Clinic prior to 1951 is not known. Routine ophthalmoscopic examinations were not done until 1950, and consequently, undiscovered cases of subclinical disease may have occurred that regressed to Stage 1 or Stage 2 of the period of cicatrization. All three patients seen in 1951 became completely blind; they included a set of twins, as well as a child kept in oxygen for five weeks because of multiple abscesses and severe toxicity. One child with retrolental fibroplasia in 1952 was born with agenesis of the right cerebral hemisphere; the ocular disease advanced only to Stage 2 of the active period and then regressed. The other child became completely blind. The lesion in the child born in 1953 developed to Stage 5; he was born nine days before the mother died of advanced congenital cardiac disease and massive cerebral hemorrhage. The child born in 1954 sustained massive intra-ocular hemorrhage into one eye one week after birth and now has a large mass of scar tissue in the temporal portion of the fundus; the other eye has remained normal. As dilated blood vessels were not seen in either eye, the hemorrhage may not have been a manifestation of the disease but may have been due to some unknown cause.

Half of the six patients were seen in the three-year period since our "austerity" program for oxygen therapy in prematures was begun in 1952. These three infants were given a minimum of oxygen.

Management

In the management of the premature infant, it is the practice of our pediatricians to use as low a concentration of oxygen as possible during as brief a time as feasible. This is usually during the first twenty-four to forty-eight hours only. Adequate respiration usually is established during that time, and the administration of oxygen is terminated. Occasionally, use of oxygen must be resumed for short periods. The concentration is kept at a level less than 40 per cent and frequent checks on the concentration are made.

The eyes of all prematures probably should be examined by an ophthalmologist, especially if the birth weight is less than 1,500 gm. The initial examination should be made during the first week. We prefer to use 1 drop each of a 2 per cent solution of homatropine and a 10 per cent solution of phenylephrine (neosynephrine) hydrochloride for dilating the pupil. Atropine is not used in these small infants. A small lid speculum is helpful. Re-examination is done every week during the first month and every two weeks during the second and third months. If the eyes have shown no abnormalities by the end of the third month, examinations are discontinued.

If retrolental fibroplasia develops, the pupils should be kept dilated with homatropine to prevent posterior synechiae. At the present time, no therapy appears to be of avail. Transfusions have an adverse effect if the disease is present.[4] If glaucoma develops, as it does in about a fourth of the cases of severe disease, miotics such as pilocarpine or physostigmine are often effective in reducing the intra-ocular tension.

It is important to acquaint the parents of a blind child with the educational and social facilities available to such a child.

Conclusions

Retrolental fibroplasia is a disorderly proliferation of blood vessels and connective tissue induced in the undeveloped retina of the premature infant, at least in part, by injudicious use of high concentrations of oxygen.

The lowest possible concentration of oxygen administered to the premature over the shortest possible time should be the rule in management.

Great variations in the concentration of oxygen should be avoided.

Massive Upper Gastrointestinal Bleeding

Results of Surgery during Acute Phase

W. P. EDER, M.D.
Minneapolis, Minnesota

THE treatment of the patient with massive upper gastrointestinal hemorrhage has been a controversial problem for many years. There are many who believe that blood replacement and the use of a good dietary regime is the treatment of choice. This group advises operation when:

1. The patient, after being admitted in shock and given 1,000 to 1,500 cc. of blood, exhibits signs of vascular collapse.
2. The patient cannot maintain a constant blood pressure and hematocrit in spite of 500 cc. of blood every eight hours.
3. Massive hemorrhage recurs during treatment.
4. The patient is over the age of fifty and has bled to shock levels at any time, medical treatment should be used with caution.

Under such management only those patients who demonstrate persistent bleeding or recurrent bleeding are referred for surgical management of their gastrointestinal hemorrhage. With such management the mortality rate is reported in several series to be 17 to 35 per cent. Such management places the surgeon in the position of having to salvage a rather desperate situation. In spite of this adverse situation, many patients have been salvaged by surgery and at the same time have had definitive treatment for their ulcer diathesis.

Recently the surgical approach to this problem has been emphasized by several authors who point out that continued hemorrhage and repeated hemorrhage from peptic ulcer is a grave and serious problem. They also point out that surgical management of this entity can be carried out with an over-all mortality rate which is less than that for other types of management.

Statement of the Problem

It was the impression of the surgical staff at the Minneapolis General Hospital that the number of patients seen at that institution with massive upper gastrointestinal hemorrhage from peptic disease was greater than usually seen at an average hospital. Ample opportunity presented itself to study this group of patients. Through the co-operation of the medical service all patients with gastrointestinal hemorrhage were admitted directly to the surgical service. During a five year period each such patient was evaluated by the surgical house staff and the attending surgical staff relative to the source of the patient's gastrointestinal hemorrhage, the amount of bleeding which had occurred and the feasibility of surgical treatment of his gastrointestinal hemorrhage. All patients were seen in consultation by members of the medical service and the patient's cardiovascular status and general physical status were completely evaluated. Surgical management of every patient with massive upper gastrointestinal hemorrhage was carried out.

Material and Methods

The material presented is taken from the surgical service at the Minneapolis General Hospital for the period January 1, 1950, to January 1, 1955, and represents 100 consecutive cases of massive upper gastrointestinal hemorrhage. The patients are divided into Series A and Series B.

Series A constitutes fifty patients who were seen from January 1, 1950, to July 1, 1951. The following criteria were used in the management and treatment of this group of patients:

1. The patient must have demonstrated gastrointestinal hemorrhage within seven days prior to admission.
2. The existence of "massive" upper gastrointestinal hemorrhage was defined by the presence of:
   - (a) A hemoglobin of less than 10 grams per cent or;
   - (b) A hematocrit of less than 25 volumes per cent or;
   - (c) Signs of shock as manifest by a positive tilt test, a systolic blood pressure of less than 100 mm.

Inaugural Thesis presented before the Minneapolis Surgical Society, April 7, 1955.

Hg, persistent tachycardia, peripheral vascular collapse, or;

(d) Objective evidence of massive blood loss while hospitalized.

These patients were considered to have massive gastrointestinal hemorrhage and the following principles were applied in the treatment of these patients:

1. Immediate whole blood transfusions were started and blood replacement was continued until the hemoglobin reached 14 grams per cent and the hematocrit 40 volumes per cent.
2. Concomitant medical disease must be under adequate control.
3. No bleeding diathesis should be present as ruled out by the bleeding and clotting time, prothrombin time, fractional proteins, cuff test and platelet count.

Surgical intervention was undertaken when these principles were met. The choice of procedure was left to the discretion of the operating surgeon. Deviation from these principles was permitted only when:

1. Continued bleeding as demonstrated by persistent melena or persistent hematemesis or persistent shock indicated immediate surgery in spite of an inadequate blood replacement.
2. The resumption of bleeding after all obvious bleeding had stopped indicating recurrent peptic ulceration and hemorrhage.
3. Uncontrolled medical disease.

Series B constitutes fifty patients seen between July 1, 1951, and January 1, 1955. This series differs from Series A only in that the estimation of blood loss was not done by hemoglobin, hematocrit levels or on the basis of impending shock or a positive tilt test but on the determination of plasma volume and red cell mass by the use of T-1824 vital dye. By this method adequate blood replacement could be done in relationship to quantity and to the time necessary to replace the blood loss. The definition of massive gastrointestinal hemorrhage in Series B is based upon a total circulating red cell mass deficit of more than 50 per cent. Therefore, in Series B the term "massive" gastrointestinal hemorrhage is clearly defined. When the quantity of whole blood indicated by the red cell mass deficit had been replaced, the plasma volume and red cell mass were again determined. If there had been progressive hemorrhage during the period of blood replacement, this fact was reflected at the time of the second blood volume determination and further blood was given. When a calculated normal red cell mass had been obtained, the patient was operated upon.

All of the surgical procedures were done by the surgical house staff and the attending staff of the surgical service. The results do not reflect the surgical ability of one or two surgeons but rather a group of well qualified house surgeons under the supervision of their attending staff.

No patient with esophageal varices is included in group B because other surgical principles were being applied to all patients with portal hypertension.

The surgical procedure carried out in both Series A and Series B was a subtotal gastric resection which varied in its extent from 65 per cent to 80 per cent resection. There were no vagotomies in either series.

Series A.—The average age of this group was fifty-six years. The distribution within the age group is to be found in Table I. There were no patients under the age of twenty and only one patient over the age of seventy-nine. The greatest incidence was between the age of fifty and seventy.

TABLE I. AGE DISTRIBUTION

Series A	
0-19	0
20-29	1
30-39	5
40-49	6
50-59	10
60-69	19
70-79	8
80-	1

The quantity of blood given to the patients preoperatively varied from 2,000 to 8,500 cc. The average preoperative quantity of blood was 3,500 cc.

The duration of symptoms presented by the patient varied from two hours to seven days. The average duration of symptoms prior to admission was 2.6 days. Eighteen patients (36 per cent) demonstrated melena only, fifteen patients (30 per cent) hematemesis only and seventeen patients (34 per cent) both melena and hematemesis.

The incidence of previous ulcer history was 56 per cent. No patient is included on the basis of ulcer history alone. Twelve patients gave a history of previous upper gastrointestinal bleeding;

four patients gave a history of previous perforation and twelve patients gave a history of roentgenological demonstration of peptic ulcer.

The source of the bleeding in this group of fifty patients is tabulated in Table II. The greatest incidence was due to duodenal ulcer with the second greatest incidence due to gastric ulcer. In this series there is one patient with esophageal varices and six with severe alcoholic gastritis. In one patient the source of the bleeding could not be found and an empirical gastric resection was done.

TABLE II. SOURCE OF BLEEDING

Series A

Duodenal Ulcer	30
Gastric Ulcer	12
Gastritis	6
Varices	1
Unknown	1

TABLE III. TIME—ADMISSION TO SURGERY

Series A

Less than 24 hours	16
Less than 48 hours	9
Less than 72 hours	8
Less than 96 hours	9
More than 96 hours	8

The time from admission to surgery is tabulated in Table III. One-half of the patients were operated upon within the first forty-eight hours; eight patients were operated upon between five and eighteen days after admission. This delay in their surgery was due to medical complications. Three patients had delirium tremens due to their acute alcoholism. Three patients had cardiac damage sufficient to delay their surgery until adequate management could be undertaken. One patient suffered a drug reaction and one patient developed pneumonia.

There were seven deaths in this series for an over-all mortality rate of fourteen per cent. The average number of hospital days was 18.1.

Series B.—The average age in this group was 55.2 years. The age distribution is tabulated in Table IV. The greatest incidence, again, as in Series A, is between the ages of fifty and seventy-nine. There was one patient under the age of twenty and one patient over the age of seventy-nine.

The quantity of blood given this group of patients ranged from 2,500 to 7,000 cc. The average was 4,000 cc. or 500 cc. more than in Series A.

The symptoms of the patients varied from two hours to four days prior to admission. The average was two days. Twenty patients (40 per cent) demonstrated melena only, fifteen (30 per cent) hematemesis only and fifteen (30 per cent) both melena and hematemesis.

TABLE IV. AGE DISTRIBUTION

Series B

0-19	1
20-29	1
30-39	4
40-49	7
50-59	17
60-69	10
70-79	9
80-	1

In this group the incidence of previous peptic ulcer history was 38 per cent. Only seven patients (14 per cent) had previously bled. There were two patients (4 per cent) with previous perforation. In ten patients (20 per cent) roentgenological demonstration of peptic ulcers had been made.

TABLE V. SOURCE OF BLEEDING

Series B

Duodenal ulcer	26
Gastric ulcer	14
Gastritis	5
Unknown	5

The source of the hemorrhage in this group is tabulated in Table V. Duodenal ulcers accounted for bleeding in twenty-six patients (52 per cent) and gastric ulcers in fourteen patients (28 per cent). In five patients no source of bleeding could be found and empirical gastric resection was carried out.

The time from admission to surgery varies in several important respects from Series A (Table VI).

TABLE VI. TIME—ADMISSION TO SURGERY

Series B

Less than 24 hours	0
Less than 48 hours	16
Less than 72 hours	19
Less than 96 hours	8
More than 96 hours	7

There were no patients operated upon in less than twenty-four hours. Sixteen patients were operated on within thirty-six hours and thirty-five patients were operated on within seventy-two hours. Seven patients were operated on between five and sixteen days. This delay was due to indecision on the part of two patients to accept surgical therapy, to infectious processes which required treatment in three instances, to a thromblophlebitis developing at the site of a transfusion in one instance and to alcoholic delirium tremens in one instance.

The average hospital days in this group was 17.7 days. There were three deaths in this group for an over-all mortality rate of 6 per cent.

TABLE VII. AGE DISTRIBUTION IN 100 CASES

TABLE VIII. SOURCE OF ACTIVE BLEEDING IN 100 CASES

Duodenal ulcer	56
Gastric Ulcer	26
Gastritis	11
Varices	1
Unknown	6

Combining Series A and Series B into a total of 100 consecutive patients, the data are tabulated in Tables VII, VIII, IX and X.

The over-all mortality rate for this series is 10 per cent.

Discussion

Series A represents a group of patients in which the criteria for "massive" gastrointestinal hemorrhage is somewhat vague. However, the criteria applied to this group are those criteria which have been used in assessing the presence of massive upper gastrointestinal hemorrhage prior to the use of plasma volume determination. This series, therefore, represents a group of patients who can be compared with previous series reported in the literature. That hemoglobin and hematocrit values are not adequate criteria upon which to judge a patient's operability is obvious. Undoubtedly some of the patients in this group were operated upon when their total plasma volume and red cell mass were far from normal. Also, the rate at which the transfusions were given did not coincide with the rate of blood loss and, therefore, did not permit good preoperative preparation.

The seven deaths in this series are worthy of discussion. Patient 4961 died on the fourth postoperative day of a subphrenic abscess. No source for this abscess could be found in either the suture line of the duodenal stump or the gastroenterostomy; however, it is assumed that such leakage did occur and that the over-whelming toxicity of infection precipitated his demise. Patient 2070 died on the third postoperative day following wound dehiscence and evisceration and pneumonia. Patient 2596 died on the fifteenth postoperative day of a subphrenic abscess. Patient 2650 died on the sixth postoperative day of bronchopneumonia. Patient 1067 died on the second postoperative day of an internal hernia of the small bowel. Patient 2725 died on the second postoperative day of a cerebral vascular accident. Patient 2831 died on the third postoperative day of massive atelectasis and thyrotoxicosis. These seven deaths represent probable technical errors in three patients and inadequate preoperative preparation of one patient. The three patients who expired due to evisceration and pneumonia and due to atelectasis and the cerebral vascular accident probably cannot be attributed to technical errors.

TABLE X. MORTALITY RATE IN 100 CASES

Series A	14%
Series B	6%
Series A and B	10%

It became evident after reviewing the first fifty patients that improved preoperative management of this critically ill group of patients might well reduce the mortality rate. We were also impressed with the fact that the quantity and rate of transfusions were not adequately measured. By utilizing T-1824 vital dye we were better able to determine the quantity of blood needed by our patients and the rate at which this whole blood was to be administered. By repeating the plasma volume and red cell mass just prior to surgery we were able to determine whether bleeding had continued while blood replacement had been carried out and to quickly replace this additional loss of blood just prior to surgery. In addition none of the patients were operated on within the first twenty-four hours in order to provide our medical colleagues with a better opportunity for full clinical evaluation. We had hoped by this to avoid early surgical intervention in patients with advanced cardiac disease and other controllable disease processes so that we might place these patients in a better state of operability.

In Series B there were three deaths. The first death, Case 6133, was the first patient in this series. He successfully underwent his preoperative blood replacement and subtotal gastric resection. He was well on his way to recovery when he rebled massively on the eighth postoperative day. He received twenty-seven units of blood in a period of approximately four hours. At reexploration the duodenal ulcer was found to be actively bleeding. The bleeding was controlled. However, the patient developed a wound dehiscence, wound infection and finally succumbed on his forty-first hospital day of acute yellow atrophy of the liver. Patient 77033 expired on the twelfth postoperative day of progressive hypotension which was not attributable to continued bleeding. No autopsy was obtained and it was assumed that his death was on a cardiac basis. Patient 77753 died on the fifth postoperative day of bronchopneumonia. It is interesting to note that all but the first death in this series were in patients who continued to bleed during their immediate hospital stay and were operated upon before optimal blood replacement had been given in order to attempt to control their acute hemorrhage. It was, nevertheless, gratifying in Series B to have reduced the mortality rate from 14 to 6 per cent. It is still more gratifying to know that this study extends beyond the confines of this report and that the over-all mortality rate is now less than 6 per cent.

With the availability of plasma volume determinations in all hospitals equipped with well run laboratories, the clinician has at his disposal a means of more accurately replacing the blood loss in a patient with massive upper gastrointestinal hemorrhage. In the hands of an experienced gastric surgeon, surgical principles may be applied to this clinical entity with an over-all mortality rate which approaches the mortality rate of elective gastric resection for peptic disease. With the experience gained in this group of 100 patients, the mortality rate has been reduced progressively from 14 to 6 per cent. Since the criteria of massive gastrointestinal bleeding applied to Series B is the most critical criteria applied to any series yet published, we feel that the over-all mortality rate is even more significant.

Conclusions

Gross bleeding into the upper gastrointestinal tract is a serious complication of peptic ulcer. The prolonged hypoxia from acute hemorrhage produces complications which increase the mortality and morbidity rate. The diagnosis of gross bleeding can be made with considerable ease and its quantity with reasonable accuracy. The surgical arrest of such bleeding and the treatment of the ulcer diathesis can be carried out with a relatively low mortality rate.

WHO REPORTS ON SALK VACCINE SURVEY

According to the report of the World Health Organization's study group on poliomyelitis vaccination, the United States is the only country which showed ill effects from polio vaccinations, with some of its cases traceable to faulty vaccine batches. In all, approximately 10 million children were vaccinated against polio with no subsequent effect. In addition, the study group noted that although no definite immunity period has been established in connection with Salk vaccine, it has given good protection to children between the ages of six and ten.

Norway, Sweden, South Africa, Canada, Denmark, France, Germany, the United Kingdom and the United States participated in the WHO study group meeting in Stockholm. The 40-page summary report they issued contains recommendations regarding the use of polio vaccine and is intended as a guide to world health authorities "who may be considering whether or not to begin polio vaccine programs." Topics of the report include the application of stringent safety tests; the seriousness of an existing polio situation in a country and the cost of a vaccine program in relation to available funds, timing of a vaccine program and utilization of virus strains.

Hookworm Treatment of Polycythemia Vera

JAMES MYHRE, M.D., and
FRANKLIN WALLACE, Ph.D.
Minneapolis, Minnesota

FOREIGN authors[1,2,3] have utilized hookworm for therapy of polycythemia vera. The low-grade symptomless blood loss due to this intestinal parasite theoretically sounds reasonable for relieving these patients of their plethora. This form of treatment has been given to one patient with a satisfactory result in a fourteen-month follow-up. To the best of our knowledge, this is the first use of this treatment in the United States.

Case Report

The patient was a fifty-one-year old white woman, a school teacher in whom a diagnosis of polycythemia vera was made in 1937. At that time she had an enlarged liver and spleen. For the following fourteen years she was treated with phenylhydrazine and venesections. She was first seen by the senior author in March, 1951, when she was quite weak but actively teaching school, with a hemoglobin of 9.9 grams per cent (Evelyn) and a hematocrit of 35. There were 11,100 leukocytes, with 84 per cent neutrophiles, 2 per cent eosinophiles, 13 per cent lymphocytes and 1 per cent monocytes, and 3.55 million erythrocytes. Bone marrow studies revealed a normoblastic hyperplasia without any evidence of leukemia. Phenylhydrazine was discontinued and in five weeks the hemoglobin was 17.7 grams per cent. The highest hematocrit recorded was 65.

Venesection therapy was begun again. In the eight months remaining in 1951 she had removed by venesection 1,900 cubic centimeters of blood; in 1952, 3,200 cubic centimeters of blood; and, in 1953, 2,000 cubic centimeters of blood. The time of venesections was largely determined by symptoms of the patient and, in general, venesections were done when the hematocrit was over 55. The lowest hematocrit was 45, and at this time the patient was quite weak and quite short of breath, especially after climbing stairs. She would plan to have her venesections on a Friday so that she could recover in bed to be back at school teaching on Monday. Before the venesections she was generally extremely uncomfortable and complained of headaches, fullness in the head, unsteadiness, clumsiness, feeling flushed and weak with scattered paresthesias over her body.

On January 29, 1954, she gave 500 cubic centimeters of blood by venesection. On February 4, 1954, there were 14 grams per cent of hemoglobin (Evelyn) with 8.04 million erythrocytes; a hematocrit of 53; 16,500 leukocytes with 81 per cent neutrophiles, 13 per cent lymphocytes, 1 per cent monocytes, 4 per cent eosinophiles, 1 per cent basophiles; reticulocytes 0.9 per cent; platelets 401,000; MCV 66; MCH 17; and MCC 26 per cent. Two hundred and sixty *Ancylostoma duodenale* larvae were administered percutaneously.

The source of the hookworm larvae was a native of Iraq, and the parasites were identified as *Ancylostoma duodenale* by the unequal esophageal spears and the close approximation of the anterior end of the intestine and the esophagus in the infective larvae.

A stool specimen was mixed with powdered charcoal and incubated at room temperature for two weeks. The mixture was then placed in a Baermann funnel and the infective larvae were collected. The larvae were filtered out of the suspending water and the filter paper, with the larvae down, was again placed on five layers of gauze on the screen of a Baermann funnel and the larvae were collected a second time in clean water. The glassware used was heat sterilized but no further precautions against possible bacterial contamination were taken.

The larvae were suspended in 15 cc. of water, and from counts of 1/10 cc. samples an estimate of 260 larvae was made. The suspension was poured on a 3-inch disc of white blotting paper which was laid upon the patient's left thigh for one hour. The patient noticed a very mild local itching during the exposure and that evening more of the itching occurred. For the next ten days there was a swelling and thickening of the inoculation site with a hive-like formation that persisted for ten days.

Very shortly after this, the patient developed an upper respiratory infection as manifested by coryza and a sore throat. On February 22, 1954, she developed hoarseness and a "different" sore throat and frequently ran 0.2 degrees (F) of fever. This persisted for two weeks. On March 5, 1954, or one month after the administration of the larvae, she developed a severe night cough productive of a small amount of tannish sputum which persisted for one month. Then for nearly one month more she had a cough in the daytime productive of grey sputum. The patient was examined at weekly intervals and there were no abnormal findings in physical examination of the chest. On March 12, 1954, a chest x-ray showed findings interpreted as peribronchiolitis or perhaps a faint subsiding pneumonitis in the left lower lobe.

On March 26, 1954, or approximately six weeks after

15 Apr 55	15.3	55	27,500	25

the administration of the larvae, the patient noticed morning nausea with very occasional emesis. Her appetite decreased in general and especially for sweets. This lasted perhaps two weeks. In May, 1954, or approximately four months after the administration of the larvae, for one to two weeks she had two to three loose bowel movements per day. On June 1, 1954, with school in recess, she lost all symptoms, and began to feel very well, indeed better than she had felt in many years.

The ova first appeared in the stools eleven weeks after exposure and were then too few to quantitate. After eighteen weeks 1,100 ova were counted. Since then monthly counts have averaged 3,500, the highest figure being 5,200. The benzidine test has been intermittently negative to three plus and the Guaiac has generally been negative, although once it was three plus. We have estimated that she has fifty to seventy hookworms.

At the beginning of this therapy the hematocrit was 53, and fourteen months later it was 55 without venesections (Table I).

Résumé and Discussion

An intelligent female patient with polycythemia vera, who had given 7,100 cubic centimeters of blood by venesection over the previous three-year period, was given 260 larvae of *Ancylostoma duodenale*. She developed minor itching, distress and hives at the inoculation area on the thigh; a few days later coryza and sore throat unrelated apparently to the hookworm; eighteen days after inoculation a "different sore throat" with hoarseness and a very slight fever; one month later a very severe night cough with tannish sputum; and for the next month a daytime cough productive of grayish sputum. Six weeks after inoculation she had minor transient morning nausea with very occasional emesis and a loss of appetite for sweets. Three months after inoculation for one to two weeks she had two to three loose bowel movements per day. Since then the patient has felt very well and is pleased with her treatment. She is very gratified by not having the discomfort associated with the high hematocrit before venesection and the discomfort and weakness for two to three days after venesection. The hematocrit at the time of the beginning of treatment was 53 and one year later it was 51. During the fifth month after giving the parasites, the eosinophil count reached 44 per cent.

Brumpt[1] feels that the usual sequence of events is that three days after inoculation there is migration through the lungs with coughing which occasionally lasts up to three weeks. Then in eight days the parasites are in the duodenum and there is epigastric distress, greatest at about one month, followed by diarrhea of from four to ten loose stools per day up to two months. He feels that the diarrhea is the biggest disadvantage of this form of therapy though it can be controlled by opium preparations. In his experience, decrease in red blood cell counts began in one month and complete effect was present in three months.

The most obvious disadvantage of this treatment in the fourteen months of observation was the one month of severe night cough with a lesser day cough for approximately one more month. The patient had a severe upper respiratory infection which began promptly after exposure to the parasite, and it may well be that the patient had a combination of a separately incurred pneumonia of a minor degree with the migration of the parasites through the lungs. Certainly the upper respiratory infection began before one would expect the migration through the lungs and the coryza would not be a part of the infestation.

Epidemiologically the therapy is acceptable.

Advantages of this form of treatment appear to be that it is simple, inexpensive, and there does not appear to be need for detailed supervision or special laboratory facilities as for venesections or radio-active phosphorus therapy. There is a slow regular fall in the red blood cell count while on a completely ambulatory regime. The therapy lasts five to six years and treatment can be terminated at any time. The disadvantages are considered to be the diarrhea which can persist up to two months but can be controlled by paregoric, and, in this instance, a severe cough was the only apparent disadvantage after fourteen months' observation.

This form of therapy should be considered for hemachromatosis.[4]

Eosinophilia in Malignant Disease

DAVID G. HANLON, M.D.
Rochester, Minnesota

EOSINOPHILIA, occasionally of high degree, may be found in association with malignant disease, as exemplified in the following case.

Report of Case

The patient, a sixty-one-year-old farmer, was examined at the Mayo Clinic in November, 1954. The patient stated that he had been perfectly well until July, 1954. His previous medical history was irrelevant and his family history noncontributory. Early in July, 1954, influenzalike symptoms developed which consisted of generalized malaise, backache and a pleuritic type of pain in his chest. The patient had remained away from work for only three days, and on his return he was still plagued by migratory aches and pains, particularly low in the back. These symptoms persisted, and because the low back pain interfered with sleep, he consulted his doctor around August 1, 1954. Roentgenograms of the spinal column, stomach and colon were said to have been negative at that time. Two weeks later so-called indigestion, characterized by frequent eructations, flatulence and anorexia, developed for the first time. During his illness of four and one-half months' duration he lost approximately 10 to 15 pounds. Ten days prior to examination at the clinic a purpuric area appeared without trauma in the left forearm and this was followed by similar lesions on both legs.

Careful systemic review revealed that the patient had experienced a few night sweats and also two nosebleeds, the latter just prior to examination at the clinic. In addition on a few occasions he had noticed some blood in his stools. He was somewhat constipated and attributed this to a reduced intake of food.

Physical examination was not remarkable except for evidence of loss of weight and the purpuric lesions on both legs and one on the left forearm. In the center of each purpuric lesion there was a clear zone in which a thrombosed vein could be palpated. These lesions were interpreted as being due to segmental superficial thrombophlebitis. No abdominal masses were palpable and rectal examination gave negative results.

Laboratory studies were reported as follows: The urine was normal. The value for hemoglobin was 14.0 gm. per 100 cc. of blood; erythrocytes numbered 3,950,000 and leukocytes 13,400 per cubic millimeter of blood. The differential count of leukocytes showed lymphocytes, 9 per cent; monocytes, 4 per cent; neutrophils, 45 per cent; eosinophils, 37 per cent; basophils, 1 per cent; metamyelocytes, 3 per cent and myelocytes, 1 per cent. One normoblast was seen. The platelet count was 90,000 per cubic millimeter of blood. The sedimentation rate was 29 mm. in 1 hour by the Westergren method. The sulfobromophthalein test of liver function revealed 20 per cent retention (grade 2). The roentgenogram of the thorax depicted a small area of fibrosis in the base of the left lung but nothing otherwise significant. Roentgenograms of the stomach and colon were negative for lesions, and a roentgenogram of the lumbar vertebrae revealed a narrowed second lumbar interspace with localized hypertrophic change.

Examination of the peripheral blood smear revealed some hypochromasia, mild polychromasia, increased rouleaux formation and considerable eosinophilia. The platelets seemed slightly reduced in number. Many clumps of malignant cells which were foreign to bone marrow were found on examination of the bone marrow, establishing the fact that the patient had a metastatic malignant lesion.

The patient was advised of the findings and dismissed from our care on November 23, 1954. He died on January 8, 1955. His doctor wrote that at the time of the patient's last hospitalization, a rectal tumor was palpable for the first time. At postmortem examination done elsewhere, the rectum was involved with an annular neoplasm which had infiltrated the mesentery. No gross abnormalities of other organs were found.

Tissue was forwarded to the Mayo Clinic and reviewed by one of the pathologists, Dr. Baggenstoss, who commented that the sections taken from the rectum revealed a high-grade carcinoma infiltrating the entire wall and the perirectal fat. Carcinoma cells had replaced the mucosa in a few foci but there was actually more carcinoma in the wall than in the mucosa. Most of the cells were in sheets and clumps, but in an occasional area glandular formations suggested that the lesion was an adenocarcinoma, grade 4, probably arising in the rectum. There were large areas of necrosis of tumor cells.

Sections of pancreas revealed a moderate degree of acinar dilatation but they were otherwise not remarkable. Sections of liver and spleen presented evidence of active extramedullary hematopoiesis with mitotic figures in the hematopoietic foci.

Comment

This case has three especially interesting aspects: First, the association of superficial, segmental thrombophlebitis with primary carcinoma in the

---

From the Section of Medicine, Mayo Clinic and Mayo Foundation. The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

rectum is highly unusual. Such lesions are much more frequently associated with carcinoma of the pancreas, particularly carcinoma of the tail of the pancreas, and with other retroperitoneal malignancies. Their occurrence in carcinomas of the stomach and lung and in malignant lymphomas has been noted also.

The association of a high percentage of eosinophils with a malignant lesion of the gastrointestinal tract also is unusual. Such an association was rarely commented on in the American literature until 1946, when Isaacson and Rapoport[1] reviewed the literature dealing with this subject. They collected nineteen cases of pronounced eosinophilia with cancer in which more than 10 per cent of the leukocytes were eosinophils. In addition, these authors added fifteen new cases of malignant tumor in which marked eosinophilia occurred. In twenty-seven of their thirty-four cases (79.4 per cent) metastasis had occurred. In two of the other seven cases, metastasis was not proved but was suspected. In one case metastasis was neither proved nor suspected. In the other four cases the report did not give sufficient information to determine the presence of metastasis. In seventeen of the twenty-seven cases in which metastasis was proved, hepatic involvement was noted. In twenty-nine of the thirty-four cases the malignant lesions were of epithelial origin, and in five they were of connective-tissue origin. Cases of carcinoma of the uterus, cervix, breast, penis, thyroid, adrenal pancreas, lung, stomach, gallbladder and colon as well as four cases of sarcoma were included in the group. Carcinoma of the colon was present in seven of the thirty-four cases, the largest number in a single organ. Isaacson and Rapoport[1] concluded from their study that the occurrence of eosinophilia with malignant tumors was usually indicative of dissemination and a poor prognosis.

Stickney and Heck[2] in 1944, in a general discussion on eosinophilia in which more than 6 per cent of the leukocytes are eosinophils, reported on a total of 418 cases. In tabulating the cases by degree of eosinophilia, they found malignant lesions in 5 per cent of the group in which 6 to 10 per cent of the leukocytes were eosinophils, 1.3 per cent of the group with 10 to 20 per cent eosinophils and in 4 per cent of the group with 20 per cent or more eosinophils. The type of malignant tumor was not specified in this report. Grewe and Schlitter[3] in Berlin in 1954 found among 800 cases of tumor 197 instances of eosinophilia in which more than 5 per cent of the leukocytes were eosinophils.

The cause of eosinophilia associated with malignant tumors remains obscure. Necrosis of the primary tumor or of a metastatic lesion is considered by most workers to play some role in the production of eosinophilia. It is postulated that the necrotic malignant tissue liberates protein degenerative products to which the individual has an allergic susceptibility. Although necrosis may be responsible in some way for the eosinophilia in many cases, this mechanism does not always explain the cause. Hepatic metastasis is frequently found when malignant disease is associated with eosinophilia, but the liver is not involved in all cases. The role of the liver in the production of eosinophilia is still poorly understood.

The final point of interest in this case was the leukemoid blood picture, which superficially at least might have been confused with leukemia. Metastatic malignancy, particularly when bone is involved, results in a peripheral blood picture that includes anemia, myeloid immaturity and normoblastosis. The common morphologic changes are increased rouleaux formation, toxic changes in the polymorphonuclear leukocytes, a scattering of immature myeloid cells, and one or more normoblasts. Anemia when present is ordinarily normochromic and normocytic. Low-grade leukocytosis is most commonly found, although fairly high counts can occur. In a patient with a known malignant tumor, the finding of this sort of peripheral blood picture must be regarded as evidence that the malignant tumor has metastasized, in the absence of other possible causes.

Aspiration of bone marrow may provide the simplest and most practical method of establishing the diagnosis. The importance of finding clumps of cells foreign to the marrow in smear preparations should be emphasized before a morphologic diagnosis is made. Diagnoses from single cells should be avoided. Confirmation can usually be obtained by examination of paraffin-fixed sections of bone marrow.

Summary

A case of carcinoma of the rectum is presented which is of interest because of the high degree of eosinophilia associated with it. Additional points

Seminar

THE SYSTEMIC MYCOSES

MATTHEW B. DIVERTIE, M.B., Ch.B.
and CORRIN H. HODGSON, M.D.
Rochester, Minnesota

THE systemic fungous diseases are classified pathologically as infectious granulomas and present the same problems in diagnosis and treatment as do other members of this group, with certain additional difficulties due to their own characteristics. The deep mycoses are not contagious. With the exception of the less common acute forms, they tend to be insidious in onset and pursue a slow and smoldering course in which spontaneous remissions may occur. The diagnosis of tuberculosis is made fairly frequently in these conditions, for much of the clinical and laboratory evidence tends to be nonspecific and often misleading. It is becoming increasingly common for so-called tuberculomas to be later renamed granulomas, from which Histoplasma capsulatum, Coccidioides immitis or other fungi can be isolated.

The systemic mycoses form a circumscribed group because, with the exception of true actinomycosis, each of these diseases is caused by a single species of organism. Nevertheless, partly due to the inherent ability of these organisms to adapt themselves biochemically and morphologically to changes in their environment and partly due to failure to recognize the prevalence of these infections, treatment has not shown spectacular advances. Many agents that inhibit or kill the organisms successfully *in vitro* have proved to be too toxic when used in human patients in comparable doses. In the last few years, however, some promising agents have been used with good results in treating members of this group. Since wide-spectrum antifungal agents do not exist at present, it is essential that a precise and definitive diagnosis is reached before treatment is undertaken.

For supporting evidence on which to base a diagnosis, the antibodies responsible for the state of hypersensitivity that develops in most mycotic infections may be detected by the use of cutaneous tests or may be quantitatively assessed by agglutination, precipitation or complement-fixation reactions. Once acquired, cutaneous sensitivity persists for many years and is then of little help in indicating the activity or quiescence of the disease. False positive results are frequent in sensitized persons if a high concentration of antigen is used, a circumstance that also favors a greater incidence of cross reactions, especially between blastomycin, histoplasmin and coccidioidin. False negative results often appear as an exhaustion phenomenon in the terminal stages of the disease, and the loss of established cutaneous sensitivity in known active mycotic infections may be of grave prognostic import, particularly if this is accompanied by increasing titers in the results of serologic tests. When difficulty exists in interpreting the results of cutaneous tests, help can be obtained from the serologic tests, a high titer indicating homologous cutaneous reactions and a low titer indicating that they are heterologous. Nevertheless, it is important to realize that these studies produce results which, at best, can be regarded only as suggestive or supportive. A diagnosis never should be made solely on the outcome of such tests.

Diagnostic evidence of a more direct nature is obtained from the microscopic examination of sections of tissue. The use of the periodic acid-Schiff stain has proved most effective in the identification of fungi in such specimens, although Gram's stain is to be preferred in demonstrating Actinomyces and Nocardia, whose filaments are gram-positive. Nevertheless, histologic examination has its limitations and various forms of Blastomyces dermatitidis, C. immitis and B. brasiliensis have been confused by experienced

---

mycologists. Inoculation of animals is of uncertain outcome and the most effective step in diagnosis is growing the organism on cultures made from pathologic material. Blood agar has been found to be the most satisfactory medium, with the addition, when necessary, of such antibiotics as streptomycin and penicillin to suppress bacterial contaminants. More specific media are required for certain fungi whose growth characteristics tend to be more fastidious. Final identification of the infecting agent rests on the results of culture of infected material, which should be sent to a laboratory properly equipped for the culture of fungi.

As far as general treatment is concerned, the iodides have remained the most useful therapeutic tool for many years, supported by more specific measures when such are available. Iodides may be administered orally as potassium iodide, intravenously as sodium iodide or by inhalation as ethyl iodide. Only in sporotrichosis can the iodides be regarded as specific.

Diseases Caused by Actinomycetaceae

The family Actinomycetaceae contains a varied group of organisms with characteristics intermediate between those of bacteria and fungi. They are world-wide in distribution and, before the advent of antibiotics, were responsible for the commonest of the systemic fungous infections in man. Two genera of medical importance are known. One is the parasitic, anaerobic and non-acid-fast Actinomyces and the other is the genus Nocardia, which includes organisms that are saprophytic, aerobic and variably acid-fast. Differences occur in the type of human infection that each produces.

Actinomycosis.—Human actinomycosis is caused by Actinomyces bovis or A. israeli, organisms that may be found around carious teeth, in the crypts of tonsils and in the gastrointestinal tract. They produce lesions characterized by fibrosis, the formation of granulation tissue, abscesses and multiple sinuses discharging pus in which the typical "sulfur granules" may be found. These granules are not invariably present; even when they are found, it is advisable to demonstrate the gram-positive filaments of the organism before one is certain of the diagnosis. Culture readily distinguishes the anaerobic Actinomyces from the aerobic Nocardia.

Sites of infection are in the cervicofacial region, the abdomen and the thorax in that order of frequency. In the face and neck, this disease often follows an old infection or the extraction of a carious tooth. Soft-tissue swelling, with lumpy wooden hardness and redness of the overlying skin, terminates in the development of discharging sinuses and possible involvement of bone. The abdominal form is commonest in the ileocecal region, where it may cause features suggesting acute or subacute appendicitis, with the formation of a hard mass in the right lower quadrant. Vertebral and hepatic infection, cutaneous involvement and spread to the thorax may follow. While ingested organisms are presumed to cause abdominal infection, the aspiration of the fungus is the commonest cause of thoracic actinomycosis. Pulmonary lesions tend to occur bilaterally in the lower part of the lung fields, and the mediastinum is frequently involved. A hilar mass may simulate neoplasm. The symptoms are those of a mild nonspecific respiratory infection, with the production of blood-streaked mucopurulent sputum containing the infecting organism. Pleural involvement may be part of the picture and purulent effusion may develop but more frequently the thoracic wall is invaded directly and the familiar sinuses appear, discharging their pus on the surface of the skin.

Surgical exploration of the sinus tracts should be undertaken to permit adequate drainage; excision of as much diseased tissue as possible should be accomplished, including intestinal and pulmonary resection. Penicillin in large doses over a prolonged period is the drug of choice, either by itself or in combination with a sulfonamide. Patients who have not improved after this type of chemotherapy or who have relapsed after a suitable course of treatment may respond to administration of streptomycin, chlortetracycline (aureomycin), oxytetracycline (terramycin) or chloramphenicol in large doses given for long periods. Stilbamidine also has been reported to be successful in resistant actinomycosis.[1]

Nocardiosis.—Systemic nocardiosis is chiefly pulmonary in origin, the infecting agent being Nocardia asteroides. This fungus occurs freely in nature as a saprophyte, but it causes a pulmonary infection in man that resembles tuberculosis, with subsequent pyemia and formation of multiple abscesses in the lungs, brain, subcutaneous tissue and muscles. From the two last-named sites, sinuses may drain pus onto the skin but, unlike the situation in actinomycosis, sulfur granules are seen infrequently. Not only does nocardiosis closely simulate pulmonary tuberculosis clinically but the roentgenologic appearances of the thorax are also similar and the organism is often found in a bacillary acid-fast form in sputum, pus, cerebrospinal fluid and fluid from empyema. Culture of pathologic material is the definitive method of diagnosis. Results of serologic and cutaneous tests are of little diagnostic value in human nocardiosis.

Treatment is directed along the lines already indicated for actinomycosis, but the use of sulfonamides in nocardiosis is specific. Administration of large doses should be maintained for a considerable period and continued for several months after apparent cure of the disease. Although aureomycin and chloramphenicol have been shown to be more effective than sulfadiazine *in vitro,* they were of much less value in *in vivo* studies in mice.[2]

North American Blastomycosis

First described by Gilchrist, in 1896, this disease is limited to North America and has a geographic predilection for the region of the Mississippi River valley and the southeastern part of the United States. The source of infection and the mode of transmission remain obscure but the causative agent is Blastomyces dermatitidis, a fungus that grows well on all laboratory media in common use. The disease is a chronic cutaneous or systemic or combined cutaneous and systemic infection in which the most characteristic reaction to the organism is the production of abscesses and chronic inflammation, with formation of scars.

The primary cutaneous form appears commonly on an exposed surface of the skin, particularly the face and upper limbs. The first evidence of infection is a papulopustule that slowly spreads peripherally to form a sloping purplish-red border studded with miliary abscesses, from which pus may be obtained for examination and culture. Ulceration of the center is followed by scarring, and the disease may persist in this form for many years. Hematogenous and lymphatic spread rarely occurs from these lesions; however, should it do so, the prognosis is as grave as it is in systemic spread from any other site.

As is frequently the case in the disseminated form of the deep mycoses, the site of primary infection in systemic blastomycosis is usually the respiratory tract. There is nothing specific about the onset of the disease, for the clinical picture is that of a mild respiratory infection with low-grade fever and a failure to regress. Over a period of weeks or months, symptoms of toxicity develop, and purulent sputum with attendant hemoptysis is a prominent feature. Evidence of widespread lesions in other organs finally becomes apparent, the principal sites being the skin, subcutaneous tissue and bone, of which the vertebrae and ribs are involved most often. The cutaneous lesions at this pyemic stage resemble those of the primary cutaneous form. Liver, spleen, kidneys, central nervous system and prostate are commonly infected but, in contrast to histoplasmosis and South American blastomycosis, the gastrointestinal tract is usually spared.

The mediastinum is almost invariably involved. Pulmonary lesions at first tend to be unilateral and their roentgenologic appearance may suggest that of carcinoma. As the disease progresses, cavitative or miliary tuberculosis may be simulated.

While positive cutaneous and complement-fixation reactions are valuable presumptive evidence of blastomycosis, cross reactions with histoplasmin and coccidioidin are common. If simultaneous testing with all three antigens is carried out, the true condition is usually indicated by the most pronounced cutaneous reaction. Similarly, a homologous serologic reaction will be manifested by a high titer, whereas a low titer indicates a heterologous reaction. Final diagnosis rests on the demonstration of B. dermatitidis by culture of sputum, gastric washings, pus, cerebrospinal fluid, tissue obtained for biopsy and other pathologic material.

Use of the iodides combined with electrocautery or roentgen therapy has been the prescribed plan of treatment for many years, but recurrence has been common. Of the many other agents listed, only aureomycin appears to have any pronounced inhibitory effect on the organism but even prolonged administration apparently does not produce sufficient concentration to eradicate the organism from the tissues. Other antibiotics have proved of little value. In 1948, however, it was found that one of the aromatic diamidines in low concentration caused inhibition of the growth of pathogenic fungi *in vitro*.[3] This was stilbamidine, a drug that has been used for many years in the treatment of kala-azar and that has been given with variable success in the management of multiple myeloma. Clinical trials of this drug in the treatment of the mycoses have been most encouraging.[4]

The chemical analogue 2-hydroxystilbamidine has an equivalent inhibitory effect on the growth of B. dermatitidis and good results have followed its clinical use in systemic blastomycosis. It shows no significant change after exposure to ultraviolet light and does not produce trigeminal neuropathy even after sustained administration. As with stilbamidine, however, it should be used cautiously in the presence of renal or hepatic damage. Use of 2-hydroxystilbamidine undoubtedly is the treatment of choice in systemic North American blastomycosis. It should be given intravenously in a 5 per cent solution of glucose by slow drip and in divided courses. *In vitro* studies of various antihistamines, of diethylaminoethyl fencholate and of diethylstilbestrol have shown these substances to be satisfactorily inhibitory for B. dermatitidis. Unfortunately, *in vitro* trials and clinical results are not always parallel but diethylstilbestrol has been used effectively in the treatment of cutaneous North American blastomycosis. Isolated pulmonary lesions are suitably treated by surgical resection.

South American Blastomycosis

This disease occurs most commonly in Brazil and is almost confined to South America, although one case has been reported from Costa Rica[5] and an account of the first recorded instance in the United States has been published recently.[6] The latter patient was a resident of Oregon who had worked for a time in Venezuela. This form of blastomycosis is principally a disease of rural communities, although the fungus has not been isolated from the soil and natural infection in animals has not been demonstrated. The causative agent is B. brasiliensis, a multiple budding fungus that in certain forms is readily confused microscopically with B. dermatitidis. Cultures from infected material may be made readily on all common laboratory media, although growth is characteristically slow.

Coccidioidomycosis

Coccidioidomycosis is a dust-borne disease of the dry regions of the southwestern part of the United States, with its greatest prevalence in the endemic regions of the San Joaquin valley and other parts of California, Arizona, Texas, New Mexico, Utah and Nevada. It also occurs in parts of Central and South America. The causative agent, Coccidioides immitis, contaminates the soil in these endemic zones and is probably breathed into the lungs in dust during the dry summer and autumn months.

This primary infection is symptomless in a large proportion of cases, and only a positive cutaneous reaction to the injection of coccidioidin remains as evidence of contamination. If symptoms do develop, they follow an incubation period of about two weeks and are the nonspecific features of any febrile respiratory infection, in which pleural pain with or without attendant effusion also may be present. This picture often is followed in a week or so by the development of allergic manifestations in the form of erythema nodosum, erythema multiforme, phlyctenular conjunctivitis or arthritis of the knees and ankles. These signs of sensitization, which may develop after the asymptomatic form of primary infection, are associated with a good prognosis and systemic spread rarely occurs after they appear. Roentgenologic findings are extremely variable and films may show a midzone pneumonic process or circumscribed nodular lesions that may resolve, persist as large thin-walled cavities or undergo final calcification. Hilar or mediastinal glandular enlargement or minor degrees of pleural effusion also may be seen. Ulcerative nodular cutaneous lesions and lymphadenopathy, especially of infected nodes in the neck, either heal or progress to the systemic form of the disease. They form a nonpulmonary type of primary coccidioidomycosis.

Systemic spread of the disease occurs weeks or months after the primary infection. It is a relatively infrequent sequel of initial infection but it occurs with much greater frequency in colored persons than among Caucasians. The prognosis is grave and the expectation of life is little more than a year at the most. Symptoms of toxicity, high fever, wasting and occurrence of mucopurulent sputum appear as the organism spreads to infect subcutaneous tissue, bones, testes, meninges and the viscera, with resultant formation of abscesses at these sites. The gastrointestinal tract is usually spared.

Results of precipitin and complement-fixation tests remain negative in asymptomatic and mild primary coccidioidomycosis but in severe primary infection the precipitin reaction becomes positive, reverting to negativity after a month or so. Complement-fixing antibodies appear late in severe primary infection and should disappear in a few weeks' time. Progressive increase in titer is good evidence of systemic spread. Results of skin tests with coccidioidin also become positive in all severe primary infections, and the cutaneous reaction thus induced may produce or aggravate the allergic symptoms attending the disease. As noted previously, cross reactions with blastomycin and histoplasmin may occur, and means for differentiating the three diseases already have been discussed. Confusion between inactive forms of C. immitis and B. dermatitidis may occur on microscopic examination of infected material. Culture of pus, sputum, gastric washings, cerebrospinal fluid, tissue taken for biopsy or other pathologic material provides the final diagnosis.

Large cystic cavities present in the lungs may be treated surgically, especially if recurrent hemorrhage occurs from them. Depending on the size, number and location of such lesions, anything from wedge resection to pneumonectomy may be required. Medical treatment of the primary form consists of rest in bed and supportive therapy, with adequate assurance that the leukocyte count, erythrocytic sedimentation rate, clinical and serologic findings and roentgenologic appearances have returned to normal before everyday activity is resumed.

In treatment of the systemic form of the disease, many drugs, including iodides, various dyes and heavy metals and antibiotics have been tried without success. Recent *in vitro* studies have shown that stilbamidine, certain antihistaminic drugs, actidione, prodigiosin, ethyl vanillate, methyl testosterone and the more toxic protoanemonin possess promising inhibitory properties. Clinical trial of protoanemonin did not produce encouraging results[7] but the use of prodigiosin, a purple dye extracted from cultures of Serratia marcescens (Bacillus prodigiosus) by organic solvents, has shown good results in six of fourteen patients, of whom five were moribund before treatment was commenced.[8] In general, those who showed improvement or arrest of their disease showed an absence of organisms in cultures in two weeks and healing of abscesses in about a month. Arrest of the disease was obtained in one patient who had systemic coccidioidomycosis treated with a combination of methyl testosterone and sulfonamides.[9]

Cryptococcosis

Cryptococcus neoformans, also known as Torula histolytica, causes a subacute or chronic infection of the central nervous system in man, although the lungs, solid viscera, skin and, occasionally, bone also may be attacked. This fungus occurs in nature as a saprophyte and may be isolated from the soil in many widespread regions throughout the world. Because it is a budding fungus, the infection it causes sometimes is designated "European blastomycosis," which is a misnomer in view of the fact that the disease is of world-wide incidence. The organism is one of the most indolent of the fungi, and chronic inflammatory changes and formation of pus are rarely caused by its presence. The typical lesions have a characteristic gelatinous character, with cystlike zones present in the substance of the brain from which the thick-walled budding fungus with its wide refractile capsule can be recovered. Culture of cerebrospinal fluid, sputum, gastric washings, exudates or tissue taken at biopsy on Sabouraud's medium or blood agar provides the final diagnosis. Cutaneous and serologic tests are of no help in evaluating the individual case, although specific polysaccharides have been demonstrated in the capsule of the organism.

The mode of entry of this fungus into the body is uncertain but the respiratory tract is the most likely pathway, although the skin, nasopharynx and other tissues have been incriminated. Primary or secondary cutaneous forms appear as acneiform or ulcerative lesions, while subcutaneous tumors or enlarged lymph nodes may be found, especially in the systemic form of the disease. The primary cutaneous lesions may heal spontaneously or later spread to initiate systemic dissemination of the fungus. The pulmonary form has little specificity in the way of symptoms to raise suspicion of its cause. It tends to be bilateral, although unilateral lesions may be encountered and are then suitable for surgical resection. The roentgenologic appearances are usually confused with those of neoplasm or tuberculosis, although cavitation is not frequent. Miliary lesions are noted with widespread infection, although neither mediastinum nor bone is involved in most instances, a feature that is in sharp distinction to the findings in actinomycosis, coccidioidomycosis and North American blastomycosis.

The usual form of cryptococcosis involves the central nervous system and is probably always secondary to a site of infection elsewhere in the body, in most instances the lungs. Its characteristics are those of any subacute or chronic meningoencephalitis, with the features of severe headache, nuchal stiffness, vomiting, palsies of various cranial nerves and mental disturbances of severe degree. Death occurs in a few weeks or months from respiratory failure. Cryptococcosis is a systemic disease attended in its course by remissions of variable length and with the local manifestations already mentioned.

These natural remissions make it difficult to assess the efficacy of new forms of treatment. Treatment has been unsatisfactory and the sulfonamides do not appear to have fulfilled their early promise. Iodides and penicillin are of little value, and vaccines also have failed to influence the course of the infection. Streptomycin and quinacrine hydrochloride (atabrine) have been too toxic in the doses required. Protoanemonin, a synthetic lactone that is effective in the treatment of local lesions, has produced neurotoxic symptoms severe enough to preclude its use in systemic disease. A potentially more promising development has been the isolation of substances from the broth of cultures of Bacillus subtilis or of Pseudomonas aeruginosa that inhibit the growth of C. neoformans *in vitro*. Several antihistaminic compounds, as well as the afore-mentioned antifungal agent diethylaminoethyl fencholate, have similar well-marked *in vitro* properties and may be worthy of clinical trial.

Actidione, a substance isolated from culture filtrates of Streptomyces griseus that, unlike streptomycin, is soluble in organic solvents, apparently has produced favorable effects on the course of proved cryptococcosis, although unequivocal cures have not been reported.[10] Although the temperature curves and clinical courses were slightly improved in a series of ten treated patients, most of them died. In two others, the cerebrospinal fluid remained sterile for two months after treatment with actidione.[11] These results are neither substantial nor sustained but, for want of a better drug, actidione may still continue to be used in this disease. Nausea and vomiting have been the only observed side effects. The use of fever therapy has been suggested as an adjuvant, since a higher body temperature artificially induced in mice has been shown to enhance their resistance to infection by cryptococci.[12]

Good results have been obtained after the surgical resection of focal pulmonary lesions when the stigmas of systemic dissemination could not be found.

Histoplasmosis

It was noted about a decade ago that many people living in the central Mississippi River valley and in the Ohio River valley had extensive pulmonary calcification with negative cutaneous reactions to tuberculin and coccidioidin but positive cutaneous reactions to histoplasmin. It is now accepted that histoplasmosis is not the invariably fatal condition it once was thought to be. In fact, it closely resembles coccidioidomycosis in being a highly infectious primary pulmonary disease that often is asymptomatic and that undergoes systemic dissemination in a minority of cases. Pulmonary calcification is a common sequel and tends to be diffuse and bilateral. It may be confused with healed tuberculosis or coccidioidomycosis.

The offending agent is Histoplasma capsulatum, an organism of world-wide incidence that has been isolated from the soil of endemic zones. It has a special affinity for the cells of the reticuloendothelial system, the disease thus being a reticuloendothelial cytomycosis. Cryptococcosis, North American blastomycosis and tuberculosis have been found in association with histoplasmosis, and it would appear that a reinfection or reactivation form of histoplasmosis may occur. After entrance of the organism, cutaneous reactions to histoplasmin become positive and persist probably for life. Complement-fixation tests on the other hand regress from a positive reaction in high titer early in the infection to a negative reaction. Roentgenograms show multiple scattered pneumonic or nodular zones in both lung fields and hilar adenopathy in the majority of cases. Pulmonary lesions occasionally are localized to one or two regions of a lung and may be amenable to surgical removal after the primary phase has passed. As already mentioned, multiple calcified foci are the residual evidence of infection by H. capsulatum.

The systemic form of the disease may follow a minority of primary pulmonary infections, but the primary site frequently occurs in the oropharynx or skin, where papules, plaques or punched-out ulcers are the common lesions. The intestinal tract also is a frequent portal of entry, especially in young children, with resultant ulceration of the lymphoid tissue of the small intestine. The clinical features of lymphadenopathy, hepatomegaly and splenomegaly are associated with pyrexia, emaciation, diarrhea, anemia and leukopenia. Involvement of the central nervous system and the development of solitary bony lesions are rare, although the organism can be obtained almost invariably on culture of the bone marrow. Even in the presence of widespread lesions, present opinion would lead to the belief that healing still may take place but, in general, the prognosis is extremely grave. A fading cutaneous reaction to histoplasmin and an increasing antibody titer are considered by some as indicative of serious progressive disease.

The organism can be obtained on culture of sputum, gastric washings, bone marrow, peripheral blood, tissue procured during biopsy of lymph nodes and other infected tissue on the usual media. Cross reactions may occur with blastomycin and coccidioidin in cutaneous testing but, as already mentioned, the largest reaction occurs with the homologous antigen. The same principle is followed in determining specificity when cross reactions take place in serologic tests.

Many agents have been tried in the treatment of histoplasmosis but none has met with unqualified success. The ethyl ester of vanillic acid inhibits the growth of H. capsulatum *in vitro.* Its greatest effect in animals occurs when it is given orally, suggesting that its main activity and possibly its toxicity are due to breakdown products of the drug. Toxic doses in mice cause inflammatory changes of the upper part of the gastrointestinal tract and glomerular and tubular damage in the kidneys, together with fatty degeneration and focal necrosis in the liver, toxic myocarditis and generalized capillary engorgement. The toxic dose in mice is one half its therapeutic dose. It causes drowsiness and apathy in infants; these symptoms disappear when administration of the drug is discontinued. Serious hyperventilation alkalosis of the type seen in adult encephalitis lethargica occurs in some children who are given this drug. Necropsy on persons thus treated who have died of histoplasmosis shows hepatic and renal changes similar to those found in laboratory animals. Despite these disadvantages and the added hazard of a narrow margin between toxic and therapeutic doses, ethyl vanillate has shown good results in some of the cases reported.[13] However, for the reasons already mentioned, interest in therapy with ethyl vanillate is diminishing. It is too toxic to use for any patients except those who otherwise face certain death.

Reports have been made of successful treatment of disseminated histoplasmosis with a combination of methyl testosterone and sulfonamides, with no toxicity noted during prolonged treatment.[9] Aspermia may be produced but this is reversible, as is the physiologic creatinuria resulting from its use. Jaundice was not present in the two cases reported. Report of a case in which diethylaminoethyl fencholate was employed leaves the efficacy of this drug in doubt, as other factors may have encouraged the healing process. It is not toxic and its *in vitro* inhibition of H. capsulatum is undoubted.[14] Antihistamines produce a similar effect in laboratory tests. Clinical trial of stilbamidine would not indicate any prolonged effectiveness of this drug in histoplasmosis.

As in the other systemic mycoses with isolated pulmonary lesions, surgical resection is the treatment of choice if no trace of further spread can be found.

Sporotrichosis

This is the only systemic mycosis in which iodides can be said to be specific. It is caused by Sporotrichum schenckii, which has been isolated from many natural sources, particularly soil, wood and plants, in all parts of the world. Infection follows trauma to the skin. Although the disease has been acquired from animals, there is no suspicion of spread from man to man. Unlike the other systemic fungous infections, the lungs are rarely, if ever, the site of primary infection, even in the disseminated form of the disease. The characteristic features of the localized infection make its clinical diagnosis an easy matter, but it is virtually impossible in most cases to demonstrate the presence of the fungus either in sections of tissue or on microscopic examination of pus or infected material. Culture on Sabouraud's medium or blood agar is sufficient to provide the diagnosis, and the organism grows with ease. Antibodies can be detected in the serum by agglutination, precipitation and complement-fixation tests, and positive cutaneous reactions are obtained after the injection of a heat-killed vaccine or specific polysaccharide. These tests, however, are of more academic than practical importance. Prognosis is good except in the rapidly disseminated form and in the visceral type of disease.

In the commonest form of the disease, an exposed limb, most often the arm, becomes infected following trauma to the skin, in which wood, especially the barberry thorn, is frequently the incriminated agent. The primary lesion, granulomatous in nature, develops in the subcutaneous tissue at the site of injury and later involves the skin. Subsequently, the regional lymphatic vessels are involved, along the course of which ulcerating nodules occur; enlargement of the related lymph nodes takes place later. Thin pus ultimately is discharged from the ulcerating lesions, but dissemination rarely occurs. A polymorphous epidermal type of involvement also may be found.

The disseminated form of the infection, in which pulmonary involvement does not always take place, may be encountered without any primary site of infection being defined. Hard subcutaneous nodules appear over the surface of the body. These may enlarge but do not often ulcerate. The solid viscera may be involved, the most commonly affected being the kidneys, testes and epididymides. The bony skeleton is rarely a site of pathologic change in this condition but mucous membranes, especially of the oropharynx, often are involved in the disseminated form and also may be the seat of primary disease. Final diagnosis rests on culture of the organism from infected material.

Iodides are specific in sporotrichosis and some authorities consider that their action is a selective one on the fungus itself. Others think that they exert their action by stimulating a fibroblastic reaction and encapsulation of the organism. In the few instances of disease that is resistant to iodides, success has been reported after the use of sulfonamides, although other treatment has been favorably mentioned, including hyperthermia. Promising results were obtained after use of 2-hydroxystilbamidine in systemic sporotrichosis in mice but clinical trial produced more equivocal results in the one human thus far treated.[15] Surgical excision of local lesions is contraindicated, as it is followed so frequently by prolonged suppuration, but roentgen therapy in semi-intensive filtered doses is useful in the treatment of these surface granulomas.

Comment

It is not within the scope of this presentation to debate whether or not organisms of the genus Candida produce systemic infection in man. This fungus is such a well-known contaminant of devitalized tissue in all parts of the body that doubt has been cast on its ability to cause primary systemic involvement. Since the commonest manifestations of its pathogenicity occur in readily accessible and relatively localized regions, recognition is seldom difficult and treatment is confined to topical applications.

It is advisable to regard the use of cortisone in the systemic mycoses with benign suspicion at present, as it is uncertain how harmful its effects may be in allowing spread of the disease. On the other hand, it has been suggested that it may be of some value in tiding the patient over the initial acute phase of the illness.

The systemic fungous infections remain as diseases of protean clinical manifestations that are attended in most instances by a chronic course and in which final diagnosis depends on the cultural characteristics of the causative agent. It is extremely doubtful that any universally effective antifungal agent will emerge, at least in the foreseeable future.

Current Concepts

SMOKING AND THE CARDIOVASCULAR SYSTEM

GRACE M. ROTH, Ph.D.
Rochester, Minnesota

Today one of the major medical questions is, Does smoking really have an effect on the cardiovascular system of a man in good health? To answer this question, 425 standard smoking tests were carried out on 100 normal individuals. One would suspect little difficulty in determining the effect of smoking tobacco on the circulation of normal individuals. However, all methods of measuring blood flow in man are indirect. Some of the confusion in the results of smoking tests has arisen because too little attention has been paid to certain factors during measurement of peripheral blood flow. The most important of these factors are, (1) the environmental temperature, (2) the position of the subject, particularly the extremities, (3) the taking of food and (4) the basal metabolic rate. All must be considered whenever measurements of peripheral blood flow are made. The standard smoking test, as finally devised, used the skin temperatures as a measurement of blood flow, took into consideration the four factors just listed and also required simultaneous observations of blood pressures and pulse rates.

Sixty-six standard smoking tests* were carried out on six normal subjects, four physicians and two women technicians whose basal metabolic rates ranged from —17 to +1 per cent. These studies showed that the responses to smoking of the skin temperature of the same individual varied from day to day according to the basal metabolic rate, but the increase of the blood pressure and pulse rate during smoking varied little from day to day. Thus it was necessary to determine the basal metabolic rate and skin temperatures for each study. The skin temperature of the toes of all the subjects decreased an average of 2.5°C. (4.5°F.) with a range from 1° to 4°C. (1.8° to 7.2°F.) For the fingers the average decrease was 3.2°C. (5.8°F.). The average increase of blood pressure during smoking was 20 mm. Hg systolic and 14 mm. Hg diastolic. The pulse rate increased an average of 36 beats per minute ranging from 20 to 52 beats. The electrocardiographic changes consisted of increased heart rate, decreased amplitude of T waves with inverted T waves in one instance.

Habitual smokers did not show tolerance to the effects of smoking as the skin temperatures of the extremities decreased and the blood pressure and pulse rate increased. The decrease of the skin tmperature was not related to the length of time the subject had been a smoker or the number of cigarettes smoked a day.

Additional tests were necessary to determine whether the vascular changes were due to nicotine. Two groups of tests were made. (1) Normal subjects received a solution of sodium chloride intravenously as a control and then 2 mg. of nicotine was added to the solution without the subjects' knowledge. Here again the skin temperatures decreased rapidly and definitely, the heart rate increased and the amplitude of the T waves decreased. (2) Thirty smoking tests were carried out with various commercially available denicotinized cigarettes. The vascular effects were similar to those obtained when standard cigarettes were smoked. In order to determine how much the content of nicotine in a cigarette should be decreased to bannish the vascular effects, 192 standard smoking tests were done on 29 normal subjects between the ages of twenty and thirty-six years. Six different batches of cigarettes were

GENETIC AND FAMILIAL ASPECTS OF CENTRAL NERVOUS CONDITIONS IN CHILDREN

RAY C. ANDERSON, Ph.D., M.D.
Minneapolis, Minnesota

SO numerous and varied are the hereditary diseases of the central nervous system in children that an intensive course in human genetics could be fashioned around them. Unfortunately, there still is considerable disagreement regarding the identification and classification of such diseases. Many of the present-day recognized "entities" will undoubtedly prove to be groups of independent diseases. Genetic studies will very likely help in clarifying the multiple nature of such conditions.

There has been confusion in the past regarding genetic terminology, and this has been perpetuated by the majority of medical textbooks. Thus, the term "hereditary" was formerly used to designate dominant inheritance, in other words, the appearance of a particular trait in successive generations. "Familial" was used to indicate the multiple occurrence of a trait in siblings. "Hereditary" should instead be used to indicate that the trait in question is due to biochemical units which are customarily identified as genes. On the other hand, "familial" can be used to describe the greater-than-chance clustering of traits in families, regardless of whether heredity or environment is responsible for this phenomenon.

We can group the various diseases and anomalies into various categories according to their patterns of inheritance. On the one hand, we have several rather rigid types of genetic behavior, and on the other, what we might call "hereditary tendencies."

Ninety years ago, Gregor Mendel identified the patterns of dominant and recessive inheritance. Much has been learned since, particularly with regard to the nature of the underlying particulate bodies, the chromosomes and genes, but his basic principles continue to guide genetic thinking. Man has twenty-four pairs of chromosomes, twenty-three pairs being "autosomes" and one pair being "sex chromosomes." The latter pair consists of two "X" chromosomes in the female, and an "X" and a "Y" chromosome in the male. Like the chromosomes that "carry" them, the genes occur in pairs, the two paired genes being termed "alleles." Although "dominance" and "recessiveness" are now viewed as something less than absolute, we still find these terms to be of practical value.

A dominant gene is defined as one which produces its effect regardless of the nature of its gene-mate (allele). The "effect" will appear in all individuals possessing the gene. Muscular dystrophy of the facioscapulohumeral form often occurs as a dominantly inherited disease. An affected individual in such a case will pass the predisposing gene on to 50 per cent of his children, who in turn will develop the disease in adolescent years. In some dominant diseases, the bearer of the gene may sometimes not exhibit the trait. This is termed irregular or incomplete dominance, or lack of "penetrance." Thus, in epiloia (tuberose sclerosis) there will be a spotty appearance of the condition in the family pedigree. In such families there will be outwardly ("phenotypically") normal-appearing individuals, some of whom are inwardly ("genotypically") normal and some who are genotypically abnormal. Only the latter "normals" have the predisposing gene available to pass on to the next generation.

A recessive gene is defined as one which produces an effect only when present in double dose. In other words, the dominant allele must be absent. The bearer of a double dose must of course have obtained one such gene from each parent. The parents in such cases will usually appear normal, since they will ordinarily possess

but one dose of the genes involved. Siblings subsequently born will have a one-in-four chance of getting a double dose of the gene. Since families are now usually small, recessively-determined hereditary diseases are frequently sporadic (only one in a family). It is in this type of inheritance that the parents search in vain for a taint in the family tree. When they learn that each of them evidently carried the predisposing gene, they are often relieved to know that neither one is solely to blame for the misfortune. Phenylpyruvic oligophrenia (phenylketonuria), a type of severe mental deficiency, is a classical example of this type of inheritance. Diagnosis of this disease is made by the testing of urine with ferric chloride. Recessively inherited traits are more likely to appear in marriages of blood relatives, since in such cases the parents tend to have more genes in common, the bad as well as the good.

A sex-linked gene is defined as one located on the sex chromosome. Such genes are usually recessive and usually located on the X-chromosome. This pattern of inheritance has been given widespread publicity because it is the pattern of inheritance shown by hemophilia. Female carriers of the gene appear normal since they ordinarily have a normal "cover-up" dominant allele present. The female passes the sex-linked gene on to 50 per cent of her sons, who then develop the trait because their Y-chromosome contains no cover-up allele. Progressive muscular dystrophy of the childhood type demonstrates clearly this pattern of inheritance. As the clinician is well aware, affected individuals are almost always boys. The few cases that do appear in girls may well represent a different entity. Gargoylism, though rare, has proved interesting in this respect, since it too is more common in boys. Clinically and genetically there appear to be two types of gargoylism, one type with corneal clouding and autosomal recessive inheritance, and another type with no corneal clouding and sex-linked recessive inheritance. Other types of sex-linked inheritance result if there is a dominant gene on the X-chromosome or if there is a gene on the Y-chromosome (the latter pattern then being from father to son, so-called holandric inheritance).

TABLE I. HEREDITARY CENTRAL NERVOUS SYSTEM DISEASES AND ANOMALIES IN CHILDREN

Acrocephalosyndactyly: Heredity probably of importance.
Amaurotic Idiocy, infantile (Tay-Sachs' disease): Recessive.
Anencephaly: Incidence 1/1000. Risk for CNS anomaly in later siblings 2 per cent. Risk of abortion is 20 per cent.
Ataxia, Friedreich's: Generally recessive.
Ataxia, cerebellar: Generally dominant.
Cerebral diplegia: Some cases hereditary, probably recessive.
Epilepsy: Role of heredity in dispute, though generally agreed to be of some importance. Chance for recurrence in later siblings is around 2-3 per cent.
Epiloia (Tuberose sclerosis): Irregular dominant.
Gargoylism: Generally recessive, sometimes sex-linked recessive (no corneal clouding in such cases).
Hepatolenticular degeneration (Wilson's disease): Recessive.
Hydrocephalus: Incidence 1/500. Risk for CNS anomaly in later siblings 2 per cent.
Laurence-Moon-Biedl syndrome: Recessive.
Lindau's disease (Hemangioma of cerebellum and retina): Sometimes an irregular dominant.
Microcephaly: Some cases hereditary, being recessive.
Mongolism: Role of heredity is in dispute, though probably of some importance.
Muscular atrophy, progressive infantile (Wednig-Hoffman's disease): Recessive.
Muscular atrophy, peroneal: Dominant usually, but can be recessive or sex-linked recessive.
Muscular dystrophy, facioscapulohumeral: Usually dominant.
Muscular dystrophy, childhood progressive: Usually sex-linked recessive.
Myasthenia gravis: True congenital type may be hereditary.
Myotonia congenita: Dominant.
Myotonia dystrophica: Irregular dominant.
Neurofibromatosis: Irregular dominant.
Neurofibromatosis: Irregular dominant.
Oxycephaly: Sometimes recessive, sometimes dominant.
Paramyotonia: Dominant.
Periodic paralysis: Dominant.
Phenylketonuria: Recessive.
Schilder's disease (Probably includes a variety of diseases; exact classification in dispute)
    Krabbe's disease: Recessive.
    Pelizaeus-Merzbacher disease: Recessive, usually sex-linked?
Spina bifida: Incidence 1/400. Risk for CNS anomaly in later siblings 4 per cent.
Tremor, familial: Usually dominant.
Word blindness: Probably dominant.

Not only may apparent clinical entities show different genetic patterns, but they may also be due to environmental factors. Such environmentally produced mimics are termed "phenocopies," a word coined by a geneticist working with fruit flies. Microcephaly is a good example, since it may be caused by a recessive gene, radiation during pregnancy, or by toxoplasmosis during pregnancy.

Many diseases "run in families," but show no distinct pattern of inheritance. In such cases, both heredity and environment may be involved. Even though no genetic ratios can be identified, it is possible to develop "empiric risk figures." In other words, if investigation is made of a large number of families in which there has been born a child with a particular trait, the percentage of subsequently-born affected children can be determined. If there were 300 later-born children, and if fifteen showed the trait, then the empiric risk figure would be 5 per cent (or 1-in-20), and other mothers of such children could be told that subsequent children of theirs would have a 5 per cent risk of having the trait. In such circumstances the "entity" involved may well have multiple causative factors, and the individual pedigrees must therefore be evaluated carefully.

Although the genetically determined diseases and anomalies constitute a relatively small fraction of the central nervous system difficulties of childhood, the genes themselves are not really rare. Phenylketonuria occurs but once in about 25,000 children, but approximately one in every hundred individuals is a carrier of the gene. The carrier incidence is considerably higher for the more common recessive diseases.

A tabulation (Table I) has been made of the various hereditary and familial conditions of the central nervous system which present themselves in children. Except for several specific types, mental deficiency has been omitted, since it represents a poorly understood conglomerate of conditions. Although there are undoubtedly inherited susceptibilities to infections of the central nervous system, as has been shown for poliomyelitis, this subject has been omitted because environmental factors are so predominant. Also omitted are many of the rarer conditions, such as the recently described progressive familial infantile cerebral dysfunction in which the urine is said to have the odor of maple syrup. Likewise, the psychoses have been omitted, since they should be dealt with in detail if they are to be mentioned at all.

SMOKING AND THE CARDIOVASCULAR SYSTEM

(Continued from Page 111)

used. The main stream of smoke from one cigarette of each batch contained respectively an average of 0.23, 0.55, 1.28, 1.83, 2.47 and 3 mg. of nicotine. As the concentration of nicotine in the main stream of the smoke was increased, the skin temperatures of both the fingers and toes decreased until the effects were the same as those from standard cigarettes. The lower the concentration of nicotine in the smoke the less the blood pressure and pulse rate increased from the basal level and vice versa. The increase was sharp when the concentration of nicotine was raised from 0.55 to 1.28 mg. Nicotine, then, has a most important rôle in production of the vascular changes which accompany smoking and these observations explain why the same vascular effects were obtained during the smoking of standard cigarettes and denicotinized cigarettes. Apparently, the content of nicotine in a cigarette must be decreased more than 60 per cent from that in a standard cigarette before smoking produces only slight or no vascular effects.

Since the oral administration of alcohol dilates the blood vessels of the extremities in contrast to the constriction from smoking, control smoking tests were made and on the next day the effect of smoking after the taking of alcohol was investigated. Eighty-seven smoking tests were made to determine the effect after ingestion of alcohol.† The blood pressure and pulse rate rose definitely on smoking after the ingestion of alcohol in 72 per cent of the subjects. The skin temperature of the fingers and toes decreased below the basal level on smoking after ingestion of alcohol. This seems to indicate that the alcohol did not prevent vasoconstriction from smoking.

---

†In the alcohol test 1 ounce of 95 per cent ethyl alcohol in fruit juice was administered orally and smoking was begun between thirty and sixty minutes after the ingestion at the height of the vasodilatation as measured by the increase in the skin temperature.

THE WRITTEN AND THE SPOKEN WORD

Much of the English that we hear nowadays and that we probably think of as spoken actually goes back to a written text. The President of the United States, for example, may seem to be talking informally in one of his fireside chats, but he is in fact reading from a carefully prepared manuscript. Even an interview that sounds very casual over the radio or television has probably been written out in every detail and timed to the half minute.

Thus, despite radio and television, writing is still important. Time over the air is too valuable to be subjected to the hazards of chance expression. When we wish to make sure that we have said what we wish to say as we wish to say it, we put it down in writing.

The study of writing within the framework of the communication skills has been helpful, however, in giving us a new point of view about writing and fresh approaches to it. "Good English" is no longer an arbitrary standard of formal and literary usage taught in the classroom but impractical elsewhere. It is English that is suited to a specific situation, and more often than not will be informal rather than formal.

Informal written English "lies close to current speech," to quote Porter G. Perrin, "but it is not, when written, speech exactly reproduced, partly because the written vocabulary is larger and somewhat more precise than the spoken. But its movement is largely colloquial, the movement of spoken English refined, tidied up, shorn of its looseness." This suggests that informal writing need not be regarded as such a highly specialized skill that communication between specialists and laymen must be left to the journalist as an intermediary.

Writing for others in the same professional field continues, for the most part, to be formal. The less specialized professional journals usually include both formal and informal writing.

It has been inevitable in a day of mass production that someone should have attempted to reduce the art of writing to a simple formula. The best known one is that devised by Rudolf Flesch and explained in his book *The Art of Readable Writing*. Although simple, readable writing cannot be achieved as mechanically and easily as Flesch would lead one to think, his book does give many practical, helpful suggestions about writing. Perhaps the chief value of prose engineering efforts such as Flesch's has been to encourage business and professional people to attempt to write for others outside their field. These efforts have also served to bring about a wider understanding of the relations between spoken and informal written English.

University of Minnesota

GROUP THERAPY

Many recent advances in medical therapy have made headlines—polio vaccine, cardiac surgery, and similar gains. One form of therapy has crept into the armamentarium, less spectacular but of tremendous value. This is group therapy.

To some, the very name, group therapy, causes shudders; and while they feel it may not be as catastrophic as the H Bomb, the consequences could be almost as far reaching. It is realized that from time immemorial mass therapy has been a typical device of quackery, but the understanding of modern group therapy will remove any such association.

Group therapy might well be divided into those groups conducted by lay individuals and those under professional guidance with various degrees between them. Group therapy is applicable to children as well as adults.

The groups conducted by professionally trained individuals could have as their extremes on the one end, the pure analytical type, and the repressive inspirational on the other, with again, varying degrees between.

The leadership of these groups must be supplied by the individuals qualified for the specific type of group, the psychiatrist, psychoanalyst, psychologist, or physician interested in patients' problems.

There are those who feel that group therapy developed as an expedient to war-time conditions. The first authentic groups appeared in the very early part of the century, and one of the first non-psychiatric groups appeared in this country in 1905 for tuberculous patients. The application of group psychotherapy to a subject for which it would appear almost specific, mental disorders, appeared in 1911. The psychoneurotic and psychosomatic conditions offer a most fruitful field for group therapy.

Group therapy has proven its values, and a study of the results reported from both psychiatric and non-psychiatric groups should allay the fears of those who shudder.

The dangers of group therapy lie not in the well-handled, well-studied groups, but in its adoption as a "cure yourself technique" unscreened and unguided. For those whose suspicions and prejudices cannot be overcome, one wonders whether "they are not throwing the baby out with the bath water."

Harvey O. Beek, M.D.

THE INTERNSHIP AND LICENSURE

There are growing stresses in many areas involving medical education and medical services. One of the vital areas on which much attention has been focused recently is the internship. In the symposium sponsored by the Council on Medical Education and Hospitals and presented before the Congress on Medical Education and Licensure a year ago, Dr. E. M. Leveroos of the Council Staff, provocatively issued the challenge that "the internship no longer provides sufficiently advanced educational opportunities and experience to justify its continuation as a separate and distinct phase of medical education."

Because internship is a legal requirement for licensure in some states and because of the National Board's demand for an internship prior to taking Part III of its examination, it may have been expected that licensing boards would have taken strong opposition to the challenge quoted above. Despite the pressure to shorten the total period of professional study and the criticism relating to rapid rotation through various services, four of the five panelists vigorously supported the value of the internship.

It is significant that those who supported the internship centered their defense around one major concept—that there must be a period following graduation from a medical school when the physician gradually assumes personal responsibility for definitive diagnosis and treatment. Dean Mitchell, in his discussion, referred to the internship as "a step that must be taken." The symposium, as published in the July 30, 1955, issue of *The Journal of the American Medical Association* clearly indicates the attitude of medical educators, specialty boards, and a representative cross section of the profession, the general practitioners.

There can be little doubt that, for purposes of providing time for assuming responsibility, the internship, through the years, has actually become an essential part of the total picture of medical education. The licensing boards have an interest in the internship because the true purpose of the licensing examination is essentially more practical than educational, and it attempts to cover the major branches of medical practice. Certainly, one of the major objectives of all education is to develop responsibility in the individual and, on this premise, educational effort must extend into the postgraduate area. Some of the present unrest in various state boards may represent a more critical interest in the appraisal of responsibility in the physician.

For the intern, the internship has two definite implications. First, as an essential "step," it should be considered an educational effort with a special purpose. Secondly, the intern should anticipate that his licensure examination will be largely a test of his fifth year in medical education.

The opinions expressed in the symposium are representative enough to illustrate that the internship is a vital link in the chain of events leading to the making of a competent physician. It may well serve, also, as a reflection of joint responsibility in the total field of medical education. The most important challenge involving internships is that they be improved.

S. D. Ezell, M.D.

RESEARCH AND THE PRACTICING PHYSICIAN

No one should appreciate the importance of research better than the practicing physician. Research provides the weapons and the ammunition with which he combats disease. He is peculiarly qualified to understand research. He has been initiated into its mysteries. He has trod the academic halls, been exposed to the laboratory, and learned the basic principles of science. He is familiar with the vocabulary of science and can understand the purpose of research even when at times unable to follow its intricacies.

Research, simply stated, is man's search after nature's truths, insofar as he is able to discover them. *Basic research* seeks to increase our understanding of natural phenomena without promise of practical application. *Applied research* exploits discoveries for practical ends. The former is the bedrock of scientific advance, but may be pedantic and sterile without the latter. Applied research is empirical and often falacious without a foundation in basic research.

We live in an age of science. Our highly technological society is increasingly dependent upon the fruits of research—the discovery of fundamental principles and their application to practical problems. This dependence is reflected in the phenomenal growth of research. The growth curve clearly indicates the need for progressively expanded research efforts in the future.

The essentials for a productive research program are: adequate facilities and equipment, a suitable intellectual environment; adequate means of communication; and properly trained and highly motivated *brainpower.* Only one of these prerequisites, facilities and equipment, can be bought outright. The others require something more: insight and sympathetic understanding of research and those who follow a research career.

Winston Churchill is quoted as saying that science is no more than organized curiosity. Certainly, curiosity is a principal motivating force for those who choose a research career. All of us are curious in childhood as any parent can testify, but few of us retain this curiosity (or, at least, the initiative to satisfy it) as we grow older. Perhaps we tire of the effort, perhaps we are too busy making a living, perhaps we surrender in despair—there are so many things to know and to understand. But there are some who retain this childhood curiosity and are impelled to satisfy it; to them, the most important thing in life is the discovery of nature's secrets. These are the men and women we need in research. Every such individual who is diverted to another occupation is lost to science.

Essential for productive research is a favorable intellectual environment in which the investigator may work with a minimum of distraction. The atmosphere must be sympathetic to his needs. There must be opportunity for association with other investigators. The academic soil, with its opportunities for cross-fertilization, approaches the ideal.

Adequate means of communication is more than a local problem. The individual in research must be able to compare notes with his peers, to exchange experiences and ideas, to give and take in the friendly rivalry of comment and criticism. This is the life blood of research. Textbooks, monographs and scientific journals are helpful, scientific meetings more so, but intimate personal contact is most rewarding.

Finally, there is the matter of dollars and cents. Both facilities and equipment are increasingly complex and costs mount accordingly. The economic security of the investigator is a problem and more and more men are lost to research because of economic pressures. Total funds in support of research increase, but not in proportion to the need. If we must have the results of research, we must pay the price.

Cardiovascular research, with which this writer is most familiar, is an important facet of medical research. As such, it is governed by the broad principles of biological research, and has similar needs. Its achievements are no less than those of other medical researches, although they are sometimes overshadowed by the complex problems which remain.

One tremendous recent development is cardiovascular surgery. It becomes difficult to recall the days prior to the discovery of modern surgical techniques and ancillary developments. Mechanical hearts, hypothermia, improved anesthesia, cardiac catheterization and angiocardiography, and current methods for treating cardiac emergencies originated in the research laboratory.

Epidemiological research showed that rheumatic fever follows the ubiquitous streptococcal infection. Laboratory and clinical research established the usefulness of sulphonamides and antibiotics. It then became possible for the practicing physician to prevent rheumatic fever and rheumatic heart disease. One may now confidently predict that one day rheumatic fever will be eradicated.

Not long ago, the accepted treatment for most cases of hypertension was sedation and speculative advice. Then, briefly, surgery was the answer. Now we have a spectrum of helpful drugs, none of which is perfect, but which in the aggregate are encouraging. The point is that there have been developments and advances. We look to research to find the cause of essential hypertension if we are to cure it.

Arteriosclerosis, specifically atherosclerosis, is the public enemy number one with which medicine has yet to deal effectively. We do not know its cause, empiricals have failed, and consequently, we can neither prevent nor cure it. Meanwhile, the study of this disease has mushroomed. Who can doubt the ultimate success of research here also?

Research's greatest need is for trained young people strongly motivated by curiosity. We must interest our youth in research, provide them with the opportunity to gain research experience and then help them become established in research careers. The practicing physician should be the most enthusiastic proponent of such a program. It is he who depends upon the weapons and the ammunition which research forges. It is he, also, who phrases many of the complex questions which stimulate the curiosity of the research scientist.

Charles D. Marple, M.D.
Medical Director
The American Heart Association

MEDICAL ETHICS IN ROUTINE PRACTICE

Each of our numerous medical societies has a committee called The Board of Censors. This is likely to be made up of men with vivid memories of their undergraduate and intern trials and financial tribulations. They are likely to assume that graduation from Class-A schools and fair internship ratings should be enough to exclude potential free-booters. This does not always work out ideally, but, for the most part, boards of censors have less to do with the qualifications of recent graduates than those members who are apt to travel from state to state and often represent interrupted and broken lives.

Recently, a well-domesticated elephant from a circus somewhere in the East decided to go on her own. Great disaster to the surrounding area and grief to the circus have followed up to date. Sharp hooks snagged into the animal's ears by exasperated keepers have not brought her back to the bosom of her feeding lot. A keeper in whom she has the utmost confidence is said to be the only hope for saving this worthy animal.

Perhaps this is not a dignified way to outline the work of a good board of censors or point the way as to how physicians may serve in a long medical life without being censored. It does focus attention, however, on three major premises: that an accredited graduate and licensed physician has been taught and guided by an ethically minded faculty; that the group, or medical society he wishes to join condones none of the evil practices that demean the guild as a whole; that the individual sets himself, without coercion, to fit into the field of honest medical practice and, as easily, gives example of normalcy as does the devoted husband in his conjugal relationships.

This is asking a good deal, but in a field as complicated as ours, it is noteworthy how few men deviate from normal standards despite the obvious fact that a few, through alcohol, drugs, or bad association, yield to the urge to defy our Hippocratic rules and allegiances.

Edward L. Tuohy, M.D.

INCOME MANAGEMENT

Family Service of Saint Paul has developed resources within its framework to assist families. These resources include Income Management, Homemaker Service and Temporary Child Placement.

For income management, families are referred to the agency primarily by employers or creditors when the families are not able to pay their bills and their wages have either been garnisheed or are threatened by garnishment. The service given in these situations for the most part is educational; however, some of these families need, and learn that they must have, help with their personal and/or marital problems before they can handle their indebtedness.

The request for this service is great. In 1954, more than $205,700.00 of families' own funds were handled through Family Service. The funds are disbursed in the following manner. With guides made available through the consulting home economist, a budget is made for the family. This is a low-cost budget which allows minimal

---

This is sixth in a series on Family Service of Saint Paul—a Community Chest Agency. Family Service of Saint Paul has developed resources within its framework to assist families. These resources include Income Management, Homemaker Service and Temporary Child Placement.

essentials for the family. This amount is subtracted from the total income, and the balance is prorated among the creditors.

Often, Family Service must start by taking a wage assignment to prevent pressure from any one creditor's throwing the prorate out of balance. The family's earnings are mailed to Family Service by the employer. The amount previously decided upon jointly with the family for living expenses is returned to the family and the remainder is mailed to the creditors on a pro rata basis.

One question often asked is: What do these people buy that gets them into debt? At first glance, one is likely to think that the purchase of automobiles and television sets is the primary cause. It is true that the purchase of a used automobile that soon won't run without a great deal of repair and has to be turned in on another puts the debtor in the position of paying for two automobiles instead of one. However, most of these families who own automobiles need them in their work to provide transportation to and from work because public transportation is not available.

More than half of all indebtedness is for essentials, including doctor and hospital bills. Pressure put on by hospital management to pay the bill in full before the patient leaves the hospital drives families to small loan companies. This places an increased burden on the debtor because he pays 3 per cent per month on the loan. Oftentimes, on a prorate basis, the debtor is able to pay only the interest.

Family Service has facilities in casework staff and bookkeeping to handle approximately 120 families for money management at one time. Therefore, the number accepted for this service must be limited. Families with children are given priority, and those families whose income or situation is such that the job is in jeopardy if they do not receive help are accepted. In other words, Family Service concentrates on the "hardship" cases.

Families eligible for this service from Family Service of Saint Paul must live in Ramsey County or West Saint Paul, or the wage earner must be employed in a company that contributes to the Greater Saint Paul Community Chest and Council.

(Mrs.) Lois Hoffman
Director of Case Work Services

BANKS AND INVESTMENT SERVICES

Few people realize how many services are available in a bank's investment department in addition to the basic functions of a bank, such as accepting deposits for checking or savings accounts and lending money for various purposes. If one wants a plan for the building of an estate or permanent investment of an estate, there is no better place than a bank to consult representatives with long experience. This is true primarily in the larger banks or their affiliates. Whether the account is large or small, the knowledge and research facilities are invaluable in setting up lifetime plans with periodic servicing of accounts.

Is your income burdened with heavy taxes requiring tax exemption, or do you want more income to supplement earnings from your practice? These questions are normal, day-to-day problems in a bank investment department.

Do you want a balanced investment program with growth possibilities but with a certain amount of risk, or do you want assured income? This can be worked out to the individual's needs. If your present investments require a going-over to weed out the weaker securities to improve general quality, this can be done.

If you want principal maturing for education or other purposes, a bank can supply these needs. Or, if you just want to sell or buy, no place is more logical than a bank.

If you want to safely ship securities under a blanket insurance policy to practically any place in the country with a post office address (preferably to a bank), it can easily be done through a bank's investment department.

Bonds and stocks called for redemption or to be sent in for conversion are handled by trained employees with the "know-how" in expediting these functions.

Call features can be checked, dividends claimed, and transfers made with proper taxes determined. Liquidation of estates with security holdings are routine for the staff in a bank.

Many bank research departments have extensive files and available data covering government, municipal, industrial, public utility, railroad, and other types of securities. The need for providing pertinent and thorough information for the administration of trusts in a bank or trust company affiliate make available data which would be difficult to obtain from other sources.

A bank also acts for the United States Government in the distribution and collection of all kinds of Federal obligations. Questions regarding reissuance and changes can be answered readily in a bank.

Bernard B. Knopp
Manager, Municipal Bond Department
The First National Bank of Saint Paul

SICK LEAVE AND THE TAXPAYER

Periodically, we all need a stimulus to start us thinking—particularly along specific lines. Periodically, we all might do well to review our actions with an eye toward whether we want to maintain a reasonable standard of honesty, or whether we should be good fellows. Specifically, we are leading up to the matter of a physician's certification of the need for sick leave for a Civil Service employe, though the same principles will hold for any employe.

The whole matter is best expressed in a letter to the Secretary of the Massachusetts Medical Society from the Commander of the Boston Naval Shipyard, published in the December 8, 1955, issue of *The New England Journal of Medicine*. In it, the commander points out that: (1) a sick leave application is a legal document which forms the basis for the payment of government funds; (2) each day of unnecessary and unwarranted absence contributed to excessive costs and delays; and (3) unwarranted sick benefit payment, or padded or exaggerated vouchers, add to the tax burden of all citizens, and, in addition, constitute an element of fraud.

What with all our real concern about excessive governmental expenditures, we can afford to take a realistic attitude toward sick-leave certifications and sign them only when sickness or injury physically incapacitates the employe, when the sick leave is necessary for his health.

H.G.M.

NEW LOOK

Attention of our readers is called to the use of a different type face in Minnesota Medicine, Baskerville, which is considered a more readable type than that used in the past. Another change, instituted with the publication of the January, 1956, number, is wider spacing between columns of type on each page, giving a better separation between the two columns. This also was done in the interest of easier reading.

From time to time, other changes in the format will be made with the object of improving the journal both in attractiveness and readability.

President's Letter

GROUP LIABILITY INSURANCE

The marked increase in malpractice insurance rates in 1952, and again in 1954, resulted in our Council's appointing a special committee to survey the entire field of malpractice insurance. On recommendation of this committee, the House of Delegates in May, 1955, voted to sponsor a group plan of liability insurance for Minnesota doctors, underwritten by the St. Paul-Mercury Indemnity Company.

At the same meeting, the Association also sponsored a group disability insurance program, and, though I believe both plans were explained to most of the component medical societies by our Mr. Harold Brunn, the group disability was pressed because it was necessary to have 50 per cent participation by a certain deadline to put the plan into effect. From numerous inquiries received, I feel some confusion exists and many doctors have forgotten the advantages of the group malpractice plan.

The advantages pointed out by the committee are, briefly: that increased volume of business by an experienced company will permit increased specialization of investigative personnel, defense attorneys, et cetera, needed for the peculiar problems involved in malpractice insurance; insurance will be available to members in good standing without the compulsion of buying other types of insurance to get it; an extensive and co-ordinated educational program of prophylaxis and control will be implemented; vigorous defense against all non-meritorious claims will be stressed with the purpose of eliminating the so-called "nuisance-claim settlements" which only lead to more future unwarranted claims.

The final and most important advantage is that it will afford close liaison between the insurance company and our Association in all matters, including selectivity of risks with possible exclusion of chronic offenders, furnishing of expert testimony in defense of these cases, and medical judgment as to whether a case should be defended in court or settled out of court. This same liaison will provide statistical facts and figures on which future rates will be based. This close liaison between the underwriters and the Association, in my mind, is the greatest advantage. Our Association has an exceptionally capable Medical Advisory Committee that has always been willing and anxious to serve any member threatened with a malpractice action, but they have too rarely had the opportunity. Under this plan, they will be in close consultation with the insurance company on all threatened actions and their knowledge, judgment, and experience will be invaluable.

The rates on the group plan will run about 5½ per cent lower than present standard rates. The more doctors joining the group, the greater will be the opportunity for more efficient and economic handling of cases. More important, a future reduction will be possible in the number of cases. and a corresponding probable reduction in rates.

This does not in any way involve any discrimination or condemnation of other plans or companies. It is simply that we believe that the plan and the company selected most suitably meet the needs of the Association at this time.

As our present liability contracts expire, I feel, in justice to each other and for the good of all, we should very seriously consider our Association Group Liability Insurance Plan.

R. H. Wilson

President, Minnesota State Medical Association

Medical Economics

Committee on Medical Economics,
Minnesota State Medical Association
George Earl, M.D., Chairman

STATE OF THE UNION MESSAGE

The following comments do not indicate the official position of the American Medical Association on specific items of legislation proposed in President Eisenhower's third message on the State of the Union. Such measures may be commented upon intelligently only after examination of the specific bill. The quoted paragraphs are from the message; they are followed by a brief summary of the past position of the AMA on previous measures in the same area and are furnished for background information only.

"In the last analysis, our real strength lies in the caliber of the men and women in our armed forces, active and reserve. Much has been done to attract and hold capable military personnel, but more needs to be done. This year, I renew my request of last year for legislation to provide proper medical care for military dependents and a more equitable survivors' benefit program. The administration will prepare additional recommendations designed to achieve the same objectives, including career incentives for medical and dental officers and nurses, and increases in the proportion of regular officers."

The AMA believes that dependent medical care, if authorized by Congress, should primarily utilize civilian facilities and civilian physicians, with care to be furnished in military hospitals or by physicians in uniform only in overseas areas or where civilian resources are inadequate.

The AMA vigorously supports a career incentive program adequate to attract a sufficient number of physicians and dentists to voluntary service. Only in this manner can the necessity for some form of involuntary service be reduced.

"Closely related to the mission of the defense department is the task of the federal civil defense administration. We must strengthen federal assistance to the states and cities in devising the most effective common defense."

The AMA urges greater emphasis on the medical aspects of civil defense, with adequate appropriations to permit a realistic preparation for medical emergency produced by atomic, chemical or biological attack.

"Under the 1954 amendments to the old-age and survivors' insurance program, protection was extended to some 10 million additional workers and benefits were increased. The system now helps protect nine out of ten American workers and their families against loss of income in old age or on the death of the breadwinner. The system is sound. It must be kept so. In developing improvements in the system, we must give the most careful consideration to population and social trends, and to fiscal requirements. With these considerations in mind, the administration will present its recommendations for further expansion of coverage and other steps which can be taken wisely at this time."

The AMA urges a thorough, objective and impartial study of the economic, social and political impact of Social Security, both medical and otherwise, as the sole basis for objective non-political improvements in the Act. The AMA opposes the compulsory coverage of physicians under OASI, but does not oppose their inclusion on a voluntary basis similar to that permitted ministers.

"Other needs in the area of social welfare include increased child welfare services, extension of the program of aid to dependent children."

This is a part of the Social Security Act, a thorough study of which is urged as the sole basis for any further changes.

"The nation has made dramatic progress in conquering disease—progress of profound human significance which can be greatly accelerated by an intensified effort in medical research. A well-supported, well-balanced program of research, including basic research, can open new frontiers of knowledge, prevent and relieve suffering, and prolong life. Accordingly I shall recommend a substantial increase in federal funds for the support of such a program. As an integral part of this effort, I shall recommend a new plan to aid construction of nonfederal medical research and teaching facilities and to help provide more adequate support for the training of medical research man power."

The AMA has, in the past, been a supporter of properly administered research grants and supports one-time "brick and mortar" construction grants, on a matching basis, for medical schools. The AMA has opposed "research construction" grants unco-ordinated with other federal research or construction programs. The AMA also opposes federal subsidies to educational facilities, when used for operation or maintenance, because of the virtual certainty of federal control of the institution.

> "Finally, we must aid in cushioning the heavy and rising costs of illness and hospitalization to individuals and families. Provision should be made, by federal reinsurance or otherwise, to foster extension of voluntary health insurance coverage to many more persons, especially older persons and those in rural areas. Plans should be evolved to improve protection against the costs of prolonged or severe illness. These measures will help reduce the dollar barrier between many Americans and the benefits of modern medical care."

The AMA supports voluntary health insurance plans and is convinced that their rapid growth and expansion is proof of their ability to cover all risks which can be covered under an insurance principle. Federal reinsurance is opposed as unnecessary, unworkable except as a subsidy, and dangerous to the orderly development of sound voluntary health insurance programs.

> "Other legislation will be proposed, including legislation for prepaid group health insurance for employes and their dependents."

The AMA supports the principle of contributory health insurance, on a voluntary basis, for federal employes.

> "All of us share a continuing concern for those who have served this nation in the armed forces. The commission on veterans pensions is at this time conducting a study of the entire field of veterans' benefits and will soon submit proposed improvements."

The AMA urges the provision of the finest medical care possible to veterans with service-connected illness or disability, but opposes federal medical care for illness or disability unrelated to military service.

COST OF PROPOSED MEDICAL RESEARCH

The Department of Health, Education and Welfare will be able to present good arguments for increasing its $99 million medical research allowance by another $25 million. Also, the heady prospect of balancing the budget seems to have given administrators a happy feeling of, "After all, we can afford it."

Many departments of the government share this expansive attitude, but, it must be mentioned, the budget has not yet actually been balanced. Even if the increased revenues that are resulting from the current boom manage to balance the budget this fiscal year, there is nothing to guarantee these revenues will stay at a high level. And if they do not, will the same administrators who are asking for part of the increased revenue, volunteer to take a cut in appropriations? In Washington, it doesn't seem likely.

Health, Education and Welfare Secretary Folsom was asked whether his proposed new spending would fit into the balanced budget the Administration says it is trying to achieve. Yes, he said, if the present revenues continue. This, in spite of the fact that it costs $60 billion every year to run a government that is more than $280 billion in debt.

It is at least questionable whether a government that habitually spends more than it makes until it finally owes more than four times its current income, can "afford" new luxuries.

CANCER RESEARCH MAY BENEFIT

According to "Washington Report on the Medical Sciences," principal beneficiaries of new appropriations for medical research will be cancer, mental and heart research. These funds will be allocated through the National Institutes of Health, the Public Health Service research arm.

For the National Cancer Institute, the White House will ask Congress to approve $32,437,000; for the National Heart Institute, $22,106,000; for the National Institute of Mental Health, $21,749,000. Four other institutes that will share to a lesser extent are those for Dental Research, Arthritis and Metabolic Diseases, Microbiological and Neurological Diseases and Blindness.

The National Institutes of Health budget for operating expenses was doubled. This item covers basic research in several fields and research fellowships. Indications are that Secretary Folsom favors more emphasis on fellowship awards in addition to increases in basic research.

MILITARY DEPENDENTS' HEALTH INSURANCE

One of the first bills to reach the hoppers for the medical care of military dependents was introduced in the House of Representatives by Chairman Carl Vinson (Democrat, Georgia) of the House Armed Services Committee. Under

American Association of Blood Banks, ninth annual meeting, Somerset Hotel, Boston, Massachusetts, September 3-5. Secretary, Marjorie Saunders, 725 Doctors Building, 3707 Gaston Ave., Dallas, Texas.

Chicago Medical Society, annual clinical conference, Palmer House, Chicago, February 28-March 1, 1956.

Mediclinics of Minnesota, postgraduate course sponsored by Academy of General Practice of Broward County, Fort Lauderdale, Florida. March 5-14, 1956.

International Meetings

Canadian Medical Association, Quebec, Canada, June 10-14. Secretary, Dr. Arthur D. Kelly, 150 St. George St., Toronto, Ontario, Canada.

Congress of International Anesthesia Research Society, Miami Beach, Florida, April 9-12. Write Dr. R. J. Whitacre, 13951 Terrace Road, Cleveland, Ohio.

Congress of International Society of Hematology, Hotel Somerset, Boston, Massachusetts, August 27 to September 1. Secretary, Dr. W. C. Maloney, 39 Bay State Road, Boston, Massachusetts.

Inter-American Congress of Cardiology, Havana, Cuba, November 4-10. Write Dr. Ramon Aixala, Apartado 2108, Havana, Cuba.

International Academy of Pathology, Cincinnati, Ohio, April 24 and 25. Secretary, Dr. F. K. Mostofi, Armed Forces Institute of Pathology, Washington 25, D. C.

International Congress of International College of Surgeons, Palmer House, Chicago, Illinois, September 9-13. Secretary, Dr. Max Thorek, 1516 Lake Shore Drive, Chicago, Illinois.

World Medical Association, Havana, Cuba, October 9-15. Secretary, Dr. Louis H. Bauer, 345 E. 46th St., New York 17, New York.

Tenth Inter-American Congress of the Pan American Medical Association, Mexico City, Mexico, April 15-21, 1957. Executive director, Dr. Joseph J. Eller, 745 Fifth Avenue, New York, New York.

BIBLIOGRAPHY OF MEDICAL REVIEWS

The Armed Forces Medical Library announces the publication in May of a *Bibliography of Medical Reviews.*

The bibliography, arranged by subject,, will contain approximately 800 references to review articles in clinical and experimental medicine and allied fields which have appeared in the calendar year 1955.

Copies of the *Bibliography of Medical Reviews* will be available upon request to the Director, Armed Forces Medical Library, 7th Street and Independence Avenue, Southwest, Washington 25, D. C., in the order of receipt.

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

"Psychiatric Aspects of Dysmenorrhea" will be the subject presented by Irving C. Bernstein, M.D., and John L. McKelvey, M.D., of Minneapolis at the regular meeting of the Minnesota Society of Neurology and Psychiatry at the Town and Country Club. Saint Paul, Tuesday evening, March 13, 1956.

FIRST INTERNATIONAL CONGRESS OF HUMAN GENETICS

The first International Congress of Human Genetics will be held in Copenhagen, Denmark, August 1-6, 1956. This congress is planned to cover all genetic aspects of normal and pathological characteristics in man. Any person interested in the subject of human genetics and especially of medical genetics is invited to take part in the congress.

Provisional program and further information will be sent on request. Write the Secretariat of the First International Congress of Human Genetics, University Institute for Human Genetics, 14 Tagensvej, Copenhagen, N., Denmark.

PROGRAM OF SURGERY FOR CONGENITAL CARDIAC MALFORMATIONS

A regional program of surgery for congenital cardiac malformations has been developed for out-of-state children through the joint efforts of the Children's Bureau of the United States Department of Health, Education, and Welfare and the Minnesota Crippled Children Services. The University of Minnesota Hospitals has been designated as the regional center for this surgery. A similar program for Minnesota children has been established by Minnesota Crippled Children Services, in collaboration with the regional program. In order to facilitate offering the services to Minnesota children, the University of Minnesota Hospitals will be used, for the present; however, plans are being made to include other Minnesota hospitals as participants in the program, provided that the hospitals are interested and have facilities available for this specialized service.

A detailed announcement is being forwarded to all the physicians, public health nurses, and county welfare agencies in the state. Inquiries about the program should be directed to Crippled Children Services, Medical Services Division, Department of Public Welfare, 117 University Avenue, Saint Paul 1, Minnesota.

CONTINUATION COURSES

The University of Minnesota announces a continuation course in *Endocrinology for General Physicians* which will be held at the Center for Continuation Study from April 9 to 11. Management of the more common endocrine and metabolic abnormalities will be stressed. Guest speaker will be Dr. Peter H. Forsham, associate professor of medicine and pediatrics, University of California Medical School, San Francisco. The course will be presented under the direction of Dr. C. J. Watson, professor and head, Department of Medicine.

* * *

A continuation course in *Gynecology for Specialists* will be presented by the University of Minnesota next April 12 to 14 at the Center for Continuation Study. The course will be presented under the direction of Dr. John L. McKelvey, professor and head, Department of Obstetrics and Gynecology.

* * *

Radiology for General Physicians will be the subject of a continuation course to be presented April 16 to 18 by the University of Minnesota at the Center for Continuation Study. Registrants will have an opportunity to interpret films and carry out certain techniques under the supervision of qualified instructors. Attendance will be strictly limited, and early application is essential.

F. H. Magney, M.D., Secretary

MINNEAPOLIS WOMAN SENTENCED ON ABORTION CHARGE

Re: State of Minnesota vs. Helen Hicks, also known as Helene Reznick, Mrs. Roberts and Mrs. Raynick.

On January 9, 1956, the above named defendant, twenty-two, formerly Helen Hicks of 3428 Columbus Avenue, Minneapolis, was sentenced by the Hon. Levi M. Hall, Judge of the District Court of Hennepin County, to a term of not less than one year nor more than four years in the State Reformatory for Women at Shakopee, Minnesota, on a charge of "pregnant woman attempting abortion." However, Judge Hall suspended the sentence and placed the defendant on probation for a period of two years. The defendant stated to the Court that she married Morris Reznick of Minneapolis in December, 1955. When questioned by Judge Hall, she admitted that she had performed an abortion on herself on or about June 15, 1954.

As the result of an investigation conducted in June, 1955, by officers of the Minneapolis Police Department and a representative of the Minnesota State Board of Medical Examiners, the abortion charge was lodged against the defendant and a warrant was issued for her arrest but the authorities were unable to locate her until November, 1955, when she was arrested in Chicago, Illinois. After being returned to Minneapolis, the defendant entered a plea of guilty to the charge against her before Judge Hall on November 12, 1955.

WOMAN'S AUXILIARY

RAMSEY COUNTY NEWS

Mrs. L. G. Culver

The Ramsey County Medical Auxiliary board members started the new year with a record attendance of twenty-seven present at the January board meeting. Reports given by the committee chairmen showed that the doctors' wives have not been idle the past month.

Mrs. H. F. Schroeckenstein, chairman of the Medical and Surgical Relief Committee, reported that twenty-five cartons of supplies were packaged and sent to the Maryknoll Missions and twenty cartons sent to the Episcopal Diocese.

Mrs. Ralph Olson, in charge of cancer dressings, and her committee have developed a very efficient "assembly line" in making the dressings. While the board members are attending their meeting, the committee is busy cutting and folding pads in an adjoining room. These dressings are then ready for the board members to stitch while the meeting is in session. Not only has this method proved profitable, but it is also a pleasant way to get acquainted. Many members stay after the meeting to have sandwiches and coffee and continue working in the afternoon.

A very happy and successful New Year to you all.

WHY NOT PACK THE POSTPARTUM UTERUS?

(Continued from Page 90)

From our experience, we believe that rather than say, "I have never packed a uterus," it would be better to say, "No uterus has been removed because it was not packed."

Conclusion

A series of 38,403 consecutive deliveries is presented in which 505 uteri were packed because of postpartum hemorrhage due to atony. No hysterectomy was necessary in the 505 packed cases. There was no mortality due to atonic hemorrhage in this series. Our concept of the physiology of postpartum atony is outlined in support of the use of the intrauterine pack.

In Memoriam

RICHARD CHARLES ADAMS

Dr. Richard Charles Adams, a member of the staff of the Mayo Clinic since 1937, died in Worrall Hospital in Rochester, Minnesota, on January 21, 1956. His sudden death was occasioned by a heart attack. He was forty-nine years old.

Dr. Adams was born on August 7, 1906, in Woolner, Ontario, Canada. He attended Queen's University in Kingston, Ontario, from which he received the degrees of Doctor of Medicine and Master in Surgery in 1931. From August, 1931, to January, 1932, he was an intern in the Ottawa General Hospital, Ottawa, Ontario. He then became associated in the practice of general surgery with Dr. J. J. Robertson, of Belleville, Ontario.

Dr. Adams came to Rochester, Minnesota, on October 1, 1935, as a fellow in anesthesiology in the Mayo Foundation, with the accompanying rank of first assistant in anesthesiology. On January 1, 1937, he was appointed to the staff of the Mayo Clinic as a consultant in the Section of Anesthesiology. In 1940, he received the degree of Master of Science in anesthesiology from the University of Minnesota, and in the same year he was appointed an instructor in anesthesiology in the Mayo Foundation, Graduate School, University of Minnesota. He was promoted to assistant professor in 1945, and to associate professor in 1948. From April 1, 1952, to July 1, 1953, Dr. Adams was head of the Section of Anesthesiology at the Mayo Clinic.

When he became a fellow of the Mayo Clinic, Dr. Adams interested himself in the technique of producing anesthesia by the injection of anesthetic agents into veins, a technique known as "intravenous anesthesia." He became widely known for his proficiency in this particular field, and he later carried out investigations on curare.

In 1944, Dr. Adams' book, "Intravenous Anesthesia," was published, and is regarded as an exhaustive work on the subject.

Dr. Adams was certified in 1939 as a specialist in anesthesiology by the American Board of Anesthesiology, Inc. He was a member of the Minnesota State Medical Association, the American Medical Association, the American Society for Pharmacology and Experimental Therapeutics, the Alumni Association of the Mayo Foundation, and the Society of the Sigma Xi. He was a fellow of the American Society of Anesthetists, and served as a member of the board of directors of that organization from 1945 to 1947, and as a member of the House of Delegates in 1948.

Dr. Adams was married to Miss Elma M. Finkle on May 11, 1935. Mrs. Adams and two sons, Richard, eighteen, and Robert, fourteen, survive Dr. Adams.

STEPHEN HENRY BAXTER

Dr. Stephen H. Baxter, seventy-seven, former president of the Hennepin County Medical Society, died December 7, 1955, in Minneapolis. In 1943, Dr. Baxter was president of the Minnesota State Medical Association. He was a member of the "Fifty Club" and had been a life member since 1947.

Dr. Baxter was former director of the Franklin Hospital and senior surgeon at Abbott Hospital for many years. He served on the Board of Public Welfare in Minneapolis and was a past president of the Hennepin County Tuberculosis Association. He was also a member of the board of the Elizabeth Kenny Foundation.

Born in Mechanicsville, Ohio, Dr. Baxter received his medical education at the University of Minnesota. During World War I, he served with the American Expeditionary Forces as a major in the medical corps.

He was a member of Plymouth Congregational Church, the American College of Surgeons, the Minneapolis Surgical Society, and Nu Sigma Nu fraternity.

Dr. Baxter was the nephew of Dr. J. Warren Little who was president of the State Medical Association in 1916.

He is survived by his wife; a son, Stephen H., Jr., Minneapolis; a daughter, Mrs. Benjamin Thurston, Albuquerque, N. M., and a brother, John, Minneapolis.

ROLV SIGVARD HEGGE

Dr. Rolv S. Hegge, physician and surgeon of Austin, died December 17, 1955, after an illness of several years. He was a past president of the Mower County Medical Society.

Born in Austin in 1902, Dr. Hegge attended Austin High School, St. Olaf College, and the medical school of the University of Minnesota. In 1929, he returned to Austin and entered practice with his father, Dr. O. H. Hegge.

Dr. Hegge was Mower County Health Officer for nine years. He was a member of the Westminster Presbyterian Church. He was affiliated with Masonic organizations and a member of the Austin Shrine Club. He was a member of the Minnesota State Medical Association and the American Medical Association.

His survivors include his wife; three daughters, Mrs. Robert Weik of St. Paul, Mrs. Allen Skogebo and Karen Hegge of Austin; his father, and a sister, Mrs. Theodore Heimarck, of Minneapolis.

WILLARD SAMUEL HOWARD

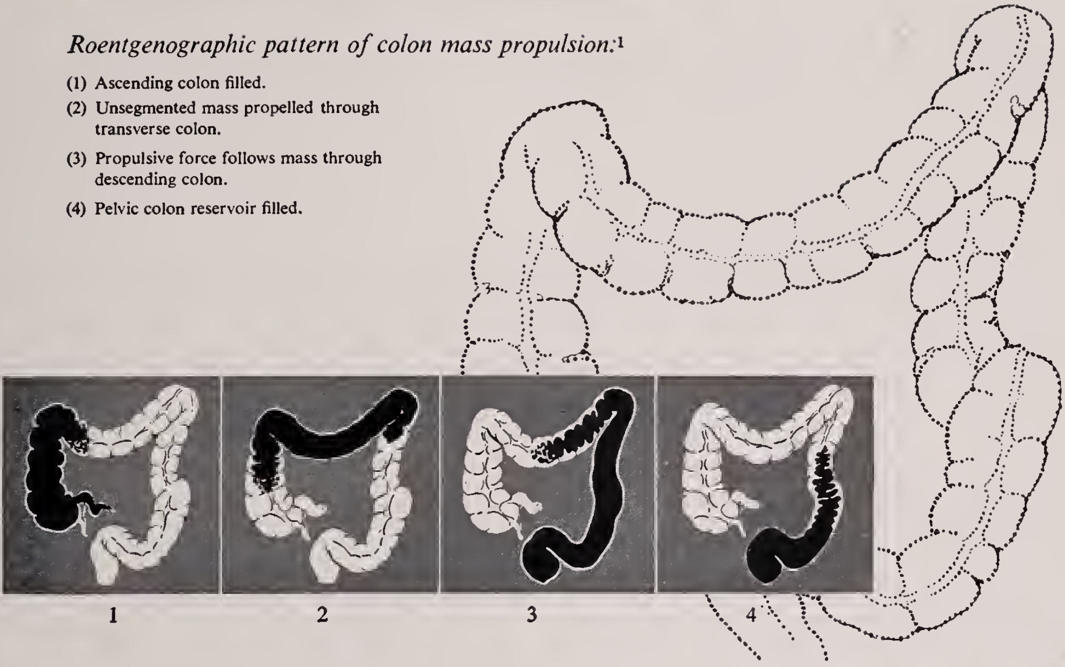
Dr. Willard S. Howard, St. Paul physician, died December 17, 1955, at the age of sixty-six. Born in Rice Lake, Wisconsin, he had been a resident of St. Paul for thirty-five years.

Dr. Howard attended the University of Illinois before serving in the medical corps as a captain during World War I. He was the St. Paul postoffice physician from 1929 to 1946, and then he became associated with the Veterans Administration at Fort Snelling.

He was a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association. He was also a member of the American Legion.

He is survived by two sons, Dr. Robert Howard of Minneapolis, and John, of St. Paul; and a sister, Mrs. Verna Lampman of Austin, Texas.

SMOOTHAGE ACTION IN CONSTIPATION



Roentgenographic pattern of colon mass propulsion:[1]

(1) Ascending colon filled.
(2) Unsegmented mass propelled through transverse colon.
(3) Propulsive force follows mass through descending colon.
(4) Pelvic colon reservoir filled.

Reestablishing Bowel Reflexes with Metamucil®

Nervous fatigue, tension, injudicious diet, failure to establish regularity, too little exercise, excessive use of cathartics—all factors which contribute to constipation.[2]

Sufficient bulk and sufficient fluid form the basic rationale of treatment of constipation. Metamucil (the mucilloid of Plantago ovata) produces a bland, smooth bulk when mixed with the intestinal contents. This bulk, through its mass alone, stimulates the peristaltic reflex and thus initiates the desire to evacuate, even in patients in whom postoperative hesitancy exists.

Correction of constipation logically, therefore, lies in the suitable adjustment of such factors as nervous fatigue and tension, improper intake of fluid, improper dietary habits, failure to respond to the call to stool, lack of physical exercise and abuse of the intestinal tract through excessive use of laxatives.[2]

The characteristics of Metamucil permit the correction of most of these factors: it provides bulk; it demands adequate intake of fluids (one glass with Metamucil powder, one glass after each dose); it increases the physiologic demand to evacuate; and it does not establish a laxative "habit." Metamucil, in addition, is inert, and also nonirritating and nonallergenic.

The average adult dose is one rounded teaspoonful of Metamucil powder in a glass of cool water, milk or fruit juice, followed by an additional glass of fluid if indicated.

Metamucil is the highly refined mucilloid of Plantago ovata (50%), a seed of the psyllium group, combined with dextrose (50%) as a dispersing agent. It is supplied in containers of one pound—also four ounces and eight ounces. G. D. Searle & Co., Research in the Service of Medicine.

SEARLE

General Interest

Minnesota physicians are invited to submit items of "general interest" concerning themselves or their colleagues to MINNESOTA MEDICINE, 2642 University Avenue, St. Paul. Only the facts are needed—who? what? where? when? why?—since items will be rewritten for conformity of style.

* * *

Dr. Robert A. Good, American Legion Memorial Heart Research professor at the University of Minnesota, has been given the Theobald Smith award for medical research. The award, consisting of $1,000 and a bronze medal, was presented at the annual meeting of the American Association for the Advancement of Science at Atlanta, Georgia, December 28. It was the second award in three months for Dr. Good, who received one from the American Academy of Pediatrics in October for his studies of agammaglobulinemia.

* * *

Dr. Hamlin Mattson, Minneapolis, spoke on "Causes of Failure in Hernia Surgery" at the annual staff meeting at St. Francis Hospital, Shakopee, on January 5.

* * *

Dr. Joseph C. Houts, Dassel, has been elected chief-of-staff of the Meeker County Memorial Hospital at Litchfield.

* * *

Guest speakers at a meeting of the Aberdeen District Medical Society, Aberdeen, South Dakota, November 2, were **Dr. Edgar G. Ingalls** and **Dr. Russell N. Frys** of Minneapolis. They presented a paper on infertility.

* * *

Dr. C. W. Froats, St. Paul, was inducted into fellowship in the American Academy of Obstetrics and Gynecology at the annual meeting of the organization in Chicago in mid-December.

* * *

At the annual business meeting of the board of governors of the Mayo Clinic, Rochester, on December 21, all officers were re-elected. They are **Dr. Samuel F. Haines**, chairman; Dr. **James T. Priestley**, vice chairman; Dr. **Hugh R. Butt**, second vice chairman, and **J. W. Harwick**, secretary.

* * *

Dr. Ian A. Brown, Minneapolis, presented an inaugural thesis entitled "Temporal Lobe Epilepsy" at a meeting of the Minnesota Society of Neurology and Psychiatry in St. Paul on January 10.

* * *

Dr. A. I. Rajala, Grand Rapids, was married to Maxine Carol Herrlinger, Deer River, at Our Savior's Lutheran Church in Doray on December 3.

* * *

At the annual meeting of the medical staff of Glenwood Hills Hospital, Minneapolis, **Dr. Irving C. Bernstein** was re-elected to serve as chief-of-staff. **Dr. Robert L. Meller** was named vice president, and **Dr. Donald Daggett**, secretary-treasurer. Retiring officers were **Dr. John Schumacher**, former vice president, and **Dr. Jennings Peteler**, former secretary-treasurer.

* * *

Dr. John S. Lundy, professor of anesthesiology in the Mayo Foundation, Rochester, has been named a corresponding member of the Association of Anaesthetists of Great Britain and Ireland. Dr. Lundy founded the section of anesthesiology at the Mayo Clinic in 1924.

* * *

Recently completed in Cannon Falls was a new clinic building, which was constructed by **Dr. Robert E. Molenaar.** In addition to housing **Dr. Molenaar's** offices, the building, which measures 35 by 50 feet, also provides quarters for two other professional men.

* * *

Dr. Walter H. Ude, Minneapolis, was elected third vice president of the Radiological Society of North America at a meeting of the organization in Chicago recently.

* * *

Newly elected officers of the Minnesota Medical Alumni Association for 1956 are **Dr. Byron B. Cochrane**, St. Paul, president; **Dr. V. J. P. Lundquist**, first vice president; **Dr. Sheldon M. Lagaard**, second vice president; **Dr. Leonard A. Borowicz**, secretary, and **Dr. James C. Mankey**, treasurer, all of Minneapolis.

Elected as members of the board of directors were **Dr. Elmer T. Ceder**, **Dr. Kristofer Hagen** and **Dr. Neil M. Palm**, all of Minneapolis.

* * *

Dr. Robert Meyer has been named health officer of Golden Valley. The village council recently appointed him to the post for a one-year term.

* * *

Dr. Frederick P. Moersch, senior consultant in the section of neurology at the Mayo Clinic and professor of neurology in the Mayo Foundation, Rochester, has been elected president of the American Board of Psychiatry and Neurology, Inc. Dr. Moersch has been a director of the board since 1948.

* * *

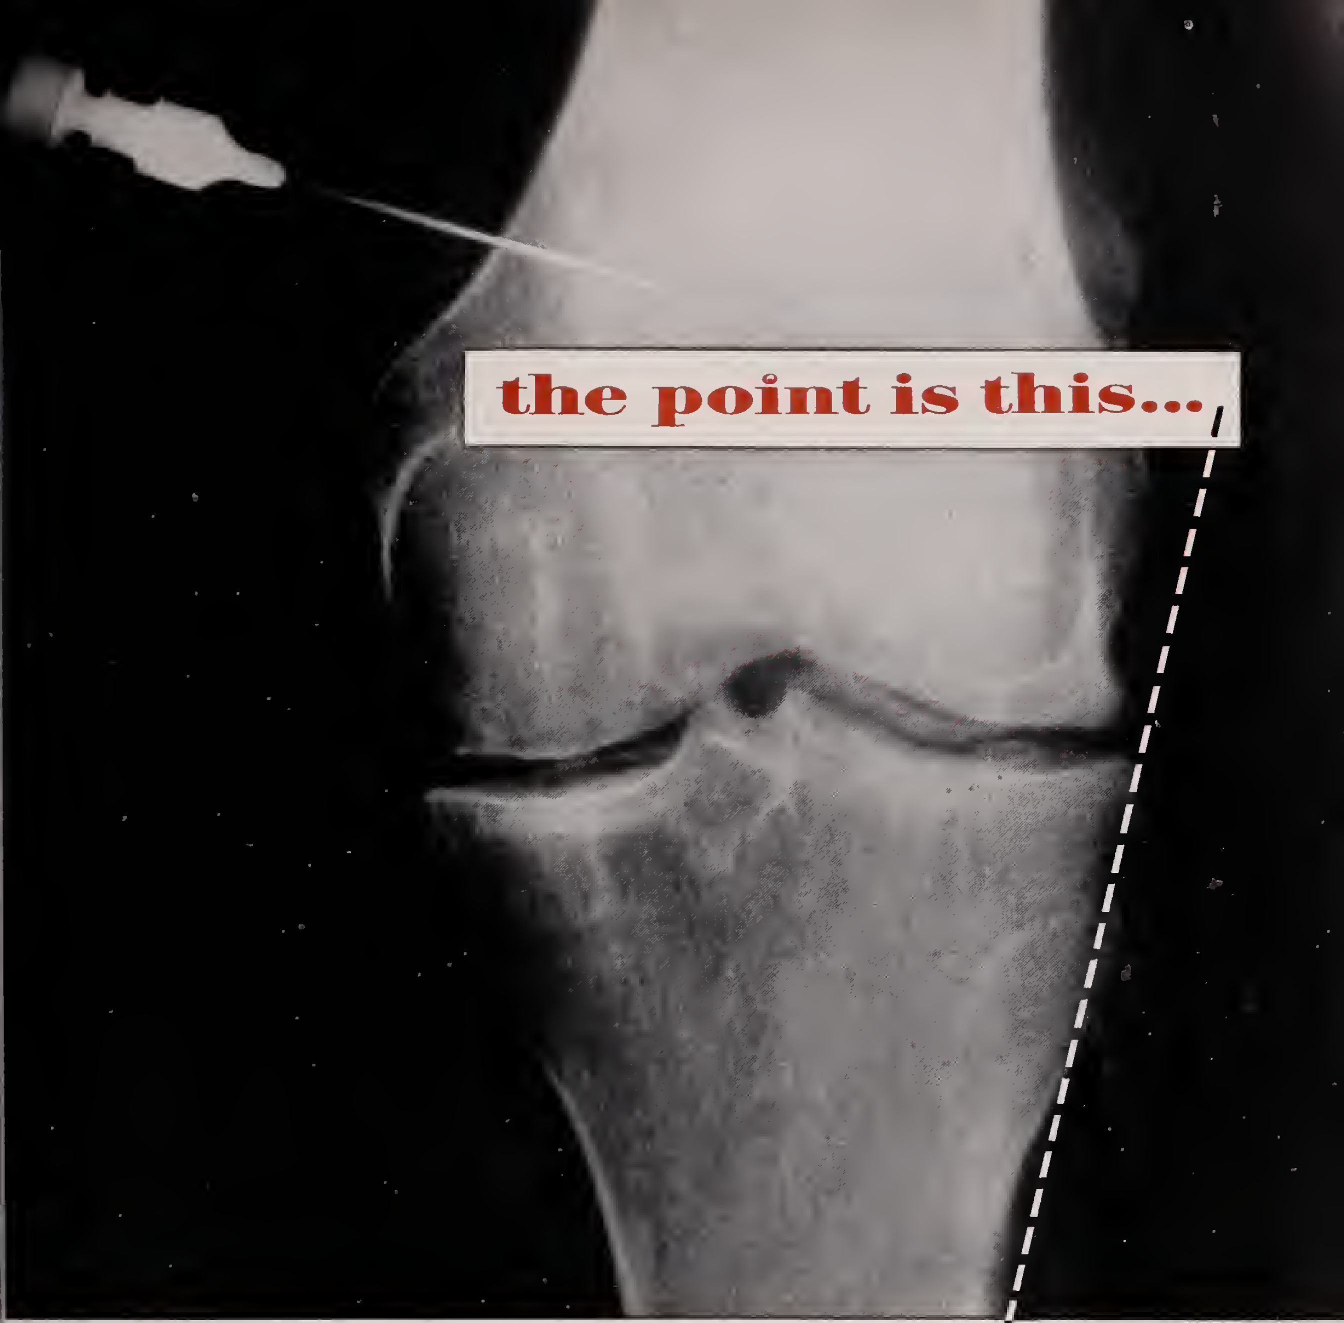
Grand prize offered by the television show "You Should Know" over KSTP-TV on Christmas Day was won by **Dr. J. G. Beaton** of Northfield. For answering a question correctly, Dr. Beaton won a trip for two to anywhere in the world plus $200 expense money. Dr. and Mrs. Beaton selected a trip to Paris as their prize.

* * *

It has been announced that **Dr. Kenneth D. Devine**, Rochester, will present a paper entitled "Carcinoma of the Nose and Paranasal Sinuses" at the convention of the American Medical Association in Chicago on June 12-14.

* * *

Dr. C. R. Stanley has retired from the staff of the



HydroCortone®-TBA

(HYDROCORTISONE TERTIARY-BUTYLACETATE, MERCK)

gives the arthritic patient more days of freedom from joint symptoms—in many patients the anti-rheumatic effect persists 2 to 10 times longer than after injection of hydrocortisone acetate. Its action is local and without systemic effect.

Worthington Clinic, Worthington, and has moved to Minneapolis. A graduate of Rush Medical College in 1911, Dr. Stanley was one of the founding partners of the Worthington Clinic in 1920. He celebrated his seventy-first birthday on December 30.

* * *

Staff officers of Asbury Methodist Hospital, Minneapolis, for 1956 are **Dr. Robert B. Potter**, president; **Dr. Harold S. Ulvestad**, vice president, and **Dr. Thomas D. Wright**, secretary-treasurer.

* * *

Dr. Frank H. Krusen, head of the section of physical medicine and rehabilitation at the Mayo Clinic and professor in the Mayo Foundation, has been given the 1956 Modern Medicine award for distinguished achievement.

* * *

Dr. Rodney F. Sturley, St. Paul, was elected president of the Minnesota Obstetrical and Gynecological Society at a meeting in St. Paul early in December. Elected as vice president of the organization was **Dr. Frederick L. Schade**, Worthington, with **Dr. Edward A. Banner**, Rochester, secretary-treasurer.

* * *

The combination office and home of **Dr. Herman Linde**, Cyrus, was totally destroyed by fire on January 3. Cause of the blaze was an overheated furnace. Immediately after the fire residents of the community announced that they planned to do whatever possible to help Dr. and Mrs. Linde rebuild.

* * *

Two University of Minnesota physicians took part in the first of a series of closed circuit telecasts entitled "Grand Rounds" on January 18. Among the specialists participating in the televised discussion of management of acute abdominal emergencies were **Dr. Owen H. Wangensteen**, professor and chief of the department of surgery at the University of Minnesota Medical School, and **Dr. Leo G. Rigler**, professor and chief of the department of radiology and physical therapy. The program was sponsored by the Upjohn Company.

* * *

Dr. Robert R. Kierland, Rochester, was re-elected assistant secretary-treasurer of the American Academy of Dermatology and Syphilology at a meeting in Chicago in early December.

* * *

Dr. Herbert F. R. Plass was elected chief of the medical staff of Abbott Hospital, Minneapolis, at a meeting on January 3. Also elected to office were **Dr. Tague C. Chisholm**, vice president; **Dr. Richard R. Fliehr**, secretary; **Dr. Herman E. Drill**, **Dr. Karl E. Sandt** and **Dr. Robert Semsch**, members of the executive committee.

* * *

Recently elected president of the International Federation of Physical Medicine, **Dr. Frank H. Krusen**, Rochester, will preside at the next congress of the organization in Copenhagen, Denmark, in August.

Dr. Thomas Lowry, chief of the medical staff of General Hospital, Minneapolis, and clinical professor of medicine at the University of Minnesota, was named to the Glen Lake Sanatorium commission by the Hennepin County board of commissioners on January 3. He succeeds **Dr. S. Marx White**, who resigned after serving on the commission for thirty-six years.

NEW LOCATIONS

Dr. W. J. Bushard, Minneapolis, has moved his office to new quarters at 849 Medical Arts Building. His telephone number has been changed to FEderal 2-7341.

* * *

Dr. Edward M. LaFond, formerly of the Minneapolis Veterans Hospital, has opened offices for the practice of orthopedic surgery in St. Mary's Building, St. Cloud.

* * *

Dr. W. R. Blomberg, after twenty years of practice at Princeton, has moved to St. Paul and opened offices for the practice of medicine.

* * *

Dr. H. M. Broker, formerly of Eden Valley, has opened offices in St. Mary's Building, St. Cloud, for the practice of surgery.

* * *

Dr. A. G. Sanderson, formerly on the staff of the Anoka State Hospital, has opened offices for the practice of medicine in Ashby.

* * *

Dr. James Lewis, formerly with the White Earth Indian Hospital at Detroit Lakes, has moved to Pine Ridge, South Dakota.

MINNESOTA BLUE SHIELD-BLUE CROSS

Enrollment in Blue Cross and Blue Shield reached a new high during 1955. Approximately 1,027,000 Minnesotans were enrolled in Blue Cross through 388,144 contracts, as of December 31, 1955. This is an increase of 11,006 contracts, representing 26,971 persons over the total as of December 31, 1954.

As of December 31, 1955, Blue Shield enrollment exceeded 729,000 persons enrolled through 275,587 contracts. This represents an increase of 21,575 contracts accounting for 58,705 persons as of December 31, 1954.

Blue Cross has long pursued the policy of offering a variety of contract benefits designed for varying hospital costs throughout the State of Minnesota.

In keeping with this progressive policy, a new nongroup policy is now being offered to Minnesotans. Called the "Optional Series" contract, the new plan affords persons the opportunity to select the room and board coverage that best fits hospital costs of the area in which they reside. Eligible applicants may select any room and board contract from $5 to $20. The new "Optional Series" contracts do not employ the deductible feature.

As a special feature of the professional relations program, a revised edition of the Blue Shield Participation Physicians' Manual was forwarded to each participating physician on December 30, 1955. This revised edition of the Participating Physicians' Manual contains essentially the same information as appeared in the previous

Cleans like magic . . . no more scrubbing with ULMER Kler-ro

ULMER

For surgical instruments, laboratory glassware, rubber goods and linens.

Soaks clean . . . removes dried blood, pyrogens, plasma, serums and mucus . . . eliminates necessity of hand scrubbing.

Will not etch glassware, leaves it sparkling clear. Will not pit stainless steel. Has a nearly neutral pH. Kler-ro does not cake but dissolves quickly and is safe and economical to use.

Write for free sample and brochure today . . .
MM—256b

Physicians & Hospitals Supply Co.
1400 Harmon Place Minneapolis 3, Minn.

edition, published in 1950. However, the revised Manual includes data pertaining to the improvements in the contract, as well as information regarding those services which have been added as benefits and the most recent edition of the Schedule of Payments.

Revised at the request of the Board of Directors, the Manual contains Blue Shield information of interest to physicians. It was written in such a manner as to be an easily adaptable reference for office personnel.

Of particular interest to physicians should be the section pertaining to the subscriber's contract which includes information about the benefits and terms of the contract. The Manual includes sections on reporting services rendered and proper completion of the medical service report, two important factors in assuring the physician and his patient of prompt payment of claims.

The brevity and clarity of the Manual is obvious, in view of the material necessarily included. Although brief, it is complete, for it contains the information needed to obtain the benefits to which the subscriber or patient is entitled under his Blue Shield contract.

MILITARY DEPENDENTS' HEALTH INSURANCE

(Continued from Page 123)

the terms of the bill, dependents will receive care at military establishments "subject to the availability of space, facilities, and capabilities of the medical staff," but emphasis is placed on a plan of prepaid health insurance. Servicemen are not compelled to enroll for the voluntary plan, which would permit them to receive medical care in either military or civilian facilities, but it is their strongest guarantee of good medical service.

There is a whole new approach to the question of cost. Uninsured dependents unable to gain admittance into military hospitals would have no legal claim for reimbursement of expenses incurred. Other new provisions specify that a serviceman will, through payroll allotment, contribute thirty per cent of the cost of the premium for coverage for his wife and children. He will bear the full cost of coverage for dependent parents. If he wishes more than basic coverage for diagnosis, treatment of acute medical and surgical conditions, treatment of contagious diseases, immunizations and maternity/infant care, he must pay the full amount of the extra premium. If insured dependents choose to receive care in a military installation, the insurance company will pay the bill. Also, at the discretion of the Secretary of Defense, minimal charges may be imposed for outpatient care of dependents at military medical facilities.

WE CORDIALLY INVITE YOUR INQUIRY for application for membership which affords protection against loss of income from accident and sickness (accidental death, too) as well as benefits for hospital expenses for you and all your eligible dependents.

BUTAZOLIDIN®

(brand of phenylbutazone)

elieves pain • improves function • resolves inflammation

Employing the serum protein-polysaccharide ratio (PR) as an objective criterion of rheumatoid activity, it has again been shown that BUTAZOLIDIN "...produces more than a simple analgesic effect in rheumatoid arthritis."[1]

Clinically, the potency of BUTAZOLIDIN is reflected in the finding that 57.6 per cent of patients with rheumatoid arthritis respond to the extent of "remission" or "major improvement."[2]

Long-term study has now shown that the failure rate with BUTAZOLIDIN in rheumatoid arthritis, and particularly in rheumatoid spondylitis, is significantly lower than with hormonal therapy.[3]

Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

THE FIGHT AGAINST TUBERCULOSIS; A AUTOBIOGRAPHY. By Francis Marion Potteng M.D. 276 pages. Illus. Price $4.00. New York: Hen Schuman, 1952.

This autobiography is especially interesting becau of the many interesting anecdotes that the author rela about his life as a boy on the farm. His vivid descri tion of his college and medical training are worthwh reading.

The death of his wife due to tuberculosis develop in the author an intense desire to learn more abo the disease. He ended up learning so much that soon became a world authority on the disease and add much to our information at a time when few were doi anything about the "White Plague" except saying th it was a hopeless disease.

Donald W. Koza, M.

HOOKWORM TREATMENT OF POLYCYTHEMIA VERA

(Continued from Page 100)

Summary

A patient with polycythemia vera was giv larvae of *Ancylostoma duodenale* for therapy chronic low-grade blood loss instead of the inte mittent large volume blood loss of venesecti which was so objectionable to the patient. T patient is well and very pleased after fourte months of observation. Without venesection, t hematocrit has remained stable. The results in o patient seem very satisfactory and further consi eration of this form of treatment and further tri is indicated.

A complete Infant Food
BAKER'S
MODIFIED MILK
Made from Grade A Milk
Liquid form
BAKER'S
MODIFIED MILK
Made from Grade A Milk
Powder form
ESPECIALLY PREPARED FOR THE FIRST YEAR OF INFANT FEEDING
For the Bottle fed Baby
THE BAKER LABORATORIES
made from
GRADE A MILK*
EITHER
POWDER OR LIQUID

Both forms of Baker's Modified Milk—Powder and Liquid—contain all requirements for complete infant nutrition and may be fed interchangeably.

The Powder form is particularly adaptable for feeding prematures, and for use as complemental or supplemental feedings.

For routine infant feeding, the Liquid is generally preferred because of its greater ease of preparation.

Both forms of Baker's Modified Milk are supplied gratis to all hospitals for your use.

Normal Dilutions

20 calories per ounce

Liquid form—1 fl. oz. milk to 1 fl. oz. water

Powder form—1 Tbsp. powder to 2 fl. oz. of water.

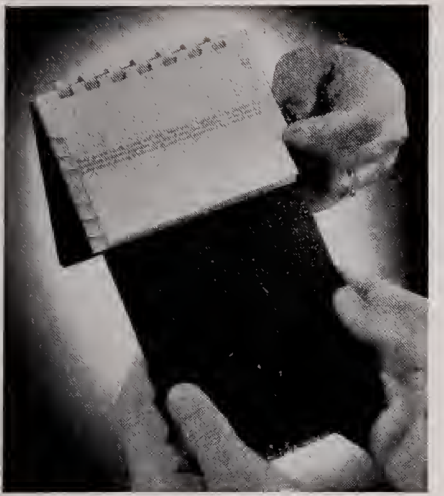
A New Departure in Near Vision Testing



Eleven pages. Over-all size of test book . . . 4¾″ wide x 8¼″ long.

The FINK NEAR VISION TEST book — *with only one size type on a page* — is a complete departure from the usual near vision test.

These are some of its advantages:

- Only one size type on a page
- Percentage rating, Jaeger designation, and inch designations on each page
- Durable plastic construction
- Completely washable
- Pages notched on left and right for easy turning
- Comfortably held by patient during test
- Has illiterate chart

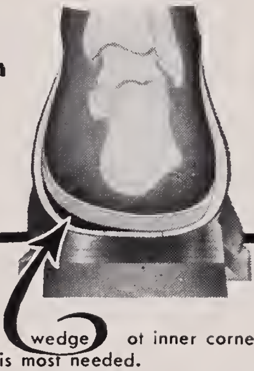
Foot-so-Port Shoe Construction and its Relation to Weight Distribution



- Insole extension and wedge at inner corner of heel where support is most needed.
- Special Supreme rubber heels are longer than most anatomic heels and maintain the appearance of normal shoes.
- The patented arch support construction is guaranteed not to break down.
- Innersoles are guaranteed not to crack, curl, or collapse. Insulated by a special layer of Texon which also cushions firmly and uniformly.
- Foot-so-Port lasts were designed and the shoe construction engineered with orthopedic advice.

NOW AVAILABLE! Men's conductive shoes. N.B.F.U. specifications. For surgeons and operating room personnel.

- By a special process, using plastic positive casts of feet, we make more custom shoes for polio, club feet and all types of abnormal feet than any other manufacturer.

Sick patients need food for therapy

Sustagen

Therapeutic Food for
Complete Nourishment

THAT MAN MUST EAT to remain well is a concept as old as medicine. But only recently has it been established (1) that nutritional needs are increased in illness; (2) that food sufficient to meet these needs is well utilized, and (3) that therapeutic nutrition prevents many of the debilitating effects of disease and injury.

Unfortunately, because of the anorexia accompanying illness, effective nutritional therapy requires added care on the part of the physician. Food comes from familiar kitchens and lacks the impressive aura of more dramatic therapeutic agents. Thus it is often difficult to convince the patient that food, too, is therapeutic—that although drugs may arrest disease only food can repair the ravages of disease.

Whatever the nutritional problem—whether caused by anorexia, mechanical difficulty in eating or limitation of gastric capacity or tolerance—only an assured food intake will solve it. The use of Sustagen, a food formulated for therapeutic nourishment, will overcome many difficulties in the therapeutic feeding of sick patients. A foundation for therapy thus may be established.

The development of Sustagen exemplifies the continuous effort of Mead Johnson & Company to provide the medical profession with products basic to the management of illness and the restoration of health.

Sustagen® is the only single food which contains all known nutritional essentials: protein, carbohydrate, fat, vitamins and minerals. It may be given by mouth or tube as the only source of food or to fortify the diet in brief or prolonged illness.

Sustagen

effective against more strains

Chloromycetin®

for today's problem pathogens

Resistant microorganisms frequently cause poor, delayed, or no response to antibiotic therapy. Because *in vitro* sensitivity tests are valuable guides in determining the antibiotic most likely to produce optimal clinical response, it is important that such tests be employed whenever possible. Recent clinical and laboratory studies[1-12] show that CHLOROMYCETIN (chloramphenicol, Parke-Davis) is effective against more strains of microorganisms than other commonly used antibiotics.

CHLOROMYCETIN is a potent therapeutic agent and, because certain blood dyscrasias have been associated with its administration, it should not be used indiscriminately or for minor infections. Furthermore, as with certain other drugs, adequate blood studies should be made when the patient requires prolonged or intermittent therapy.

GENERA

Authors

Manuscripts should be addressed to Arthur H. Wells, M.D., Editor, 915 East Fir
Street, Duluth 5, Minnesota. Telephone RA 7-6636 or JA 5-2319. Original papers prepare
for publication solely in MINNESOTA MEDICINE will be considered by the Board of Edito
providing they fulfill the following editorial standards. Manuscripts should be type
double spaced on white paper with at least 1-inch margins. The original (not a carbo
copy) is requested. The title on the first page should be under six words if possib
or divided into two parts. The author should give his highest degree, his institution
position or his relationship to a hospital or medical organization which he may
addressing. Pages should be numbered consecutively and the author's last name shou
appear at the top of each page after the first page.

Biographical references should appear on a separate sheet entitled "Bibliography." Th
should appear and be numbered consecutively in the order in which they first occur
the text (not alphabetically). Citations in the text require reference numbers if t
author's or authors' names are not used or if there is more than one reference to t
same author or group of authors. All references to author should appear in t
Bibliography and no references should be included which are not in the text. The st
and exact punctuation used in the J.A.M.A. references is requested. For a journal this i
*Author's last name, initial, initial.: title of paper. Abbreviated name of journal, volum
number: page, year.* Book references should give author, title, edition number, ci
publisher and year.

Illustrations (photographs, tables and graphs) should be submitted separately and n
combined in the text. There should be a separate sheet entitled "Illustrations" whi
contains the various types of illustrations listed separately and numbered in the ord

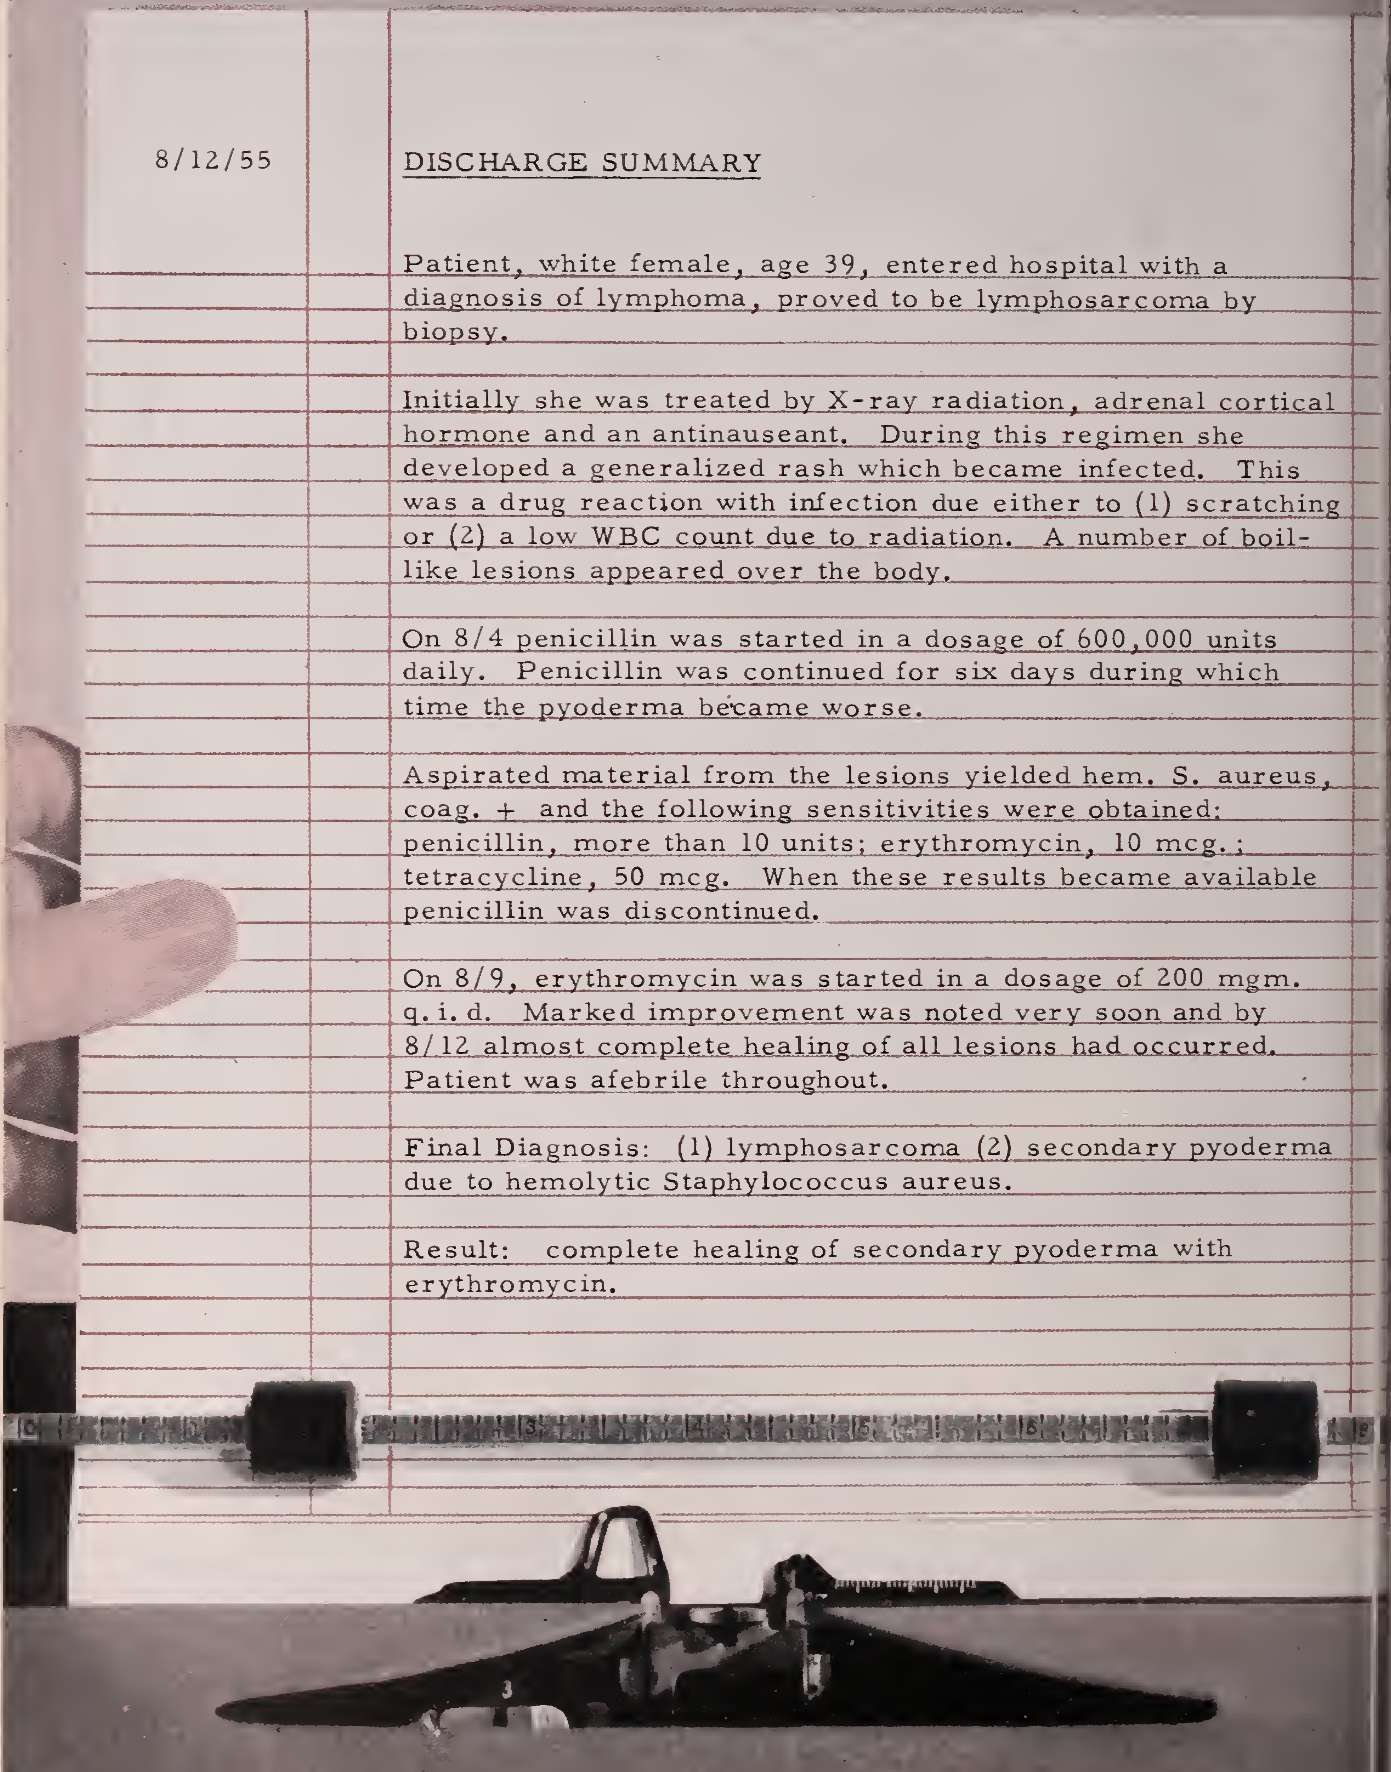
Erythromycin in treatment of pyoderma*



8/12/55

DISCHARGE SUMMARY

Patient, white female, age 39, entered hospital with a diagnosis of lymphoma, proved to be lymphosarcoma by biopsy.

Initially she was treated by X-ray radiation, adrenal cortical hormone and an antinauseant. During this regimen she developed a generalized rash which became infected. This was a drug reaction with infection due either to (1) scratching or (2) a low WBC count due to radiation. A number of boil-like lesions appeared over the body.

On 8/4 penicillin was started in a dosage of 600,000 units daily. Penicillin was continued for six days during which time the pyoderma became worse.

Aspirated material from the lesions yielded hem. S. aureus, coag. + and the following sensitivities were obtained: penicillin, more than 10 units; erythromycin, 10 mcg.; tetracycline, 50 mcg. When these results became available penicillin was discontinued.

On 8/9, erythromycin was started in a dosage of 200 mgm. q. i. d. Marked improvement was noted very soon and by 8/12 almost complete healing of all lesions had occurred. Patient was afebrile throughout.

Final Diagnosis: (1) lymphosarcoma (2) secondary pyoderma due to hemolytic Staphylococcus aureus.

Result: complete healing of secondary pyoderma with erythromycin.

Sweet*10 a new cyclamate sweetener for sugar-restricted diets!

NON-NUTRITIVE SWEETENER
6 fluid ounces
Sweet*10
10 TIMES SWEETER
than sugar
To be used in place of sugar. Sweet-10 is a water solution of 17% cyclamate calcium 0.1% Benzoic acid and 0.05% Methylparaben. Should be used only by persons who must restrict their intake of ordinary sweets.

Sweet-10 can help many of your patients. Used in place of sugar, Sweet-10 is valuable in weight control and in low salt and sugar-free diets.

Sweet-10's radio and newspaper promotion will suggest its use with coffee, tea, cereals and fruit or in cooked or baked foods. No calories . . . adds no weight.

Sweet-10's advantages over saccharin-type sweeteners will be stressed. Sweet-10 can be used in cooking, leaves no bitter aftertaste. *More economical than other cyclamate sweeteners.*

Sweet-10 is a water solution of 17% cyclamate calcium, 0.1% Benzoic acid and 0.05% Methylparaben. Also available in powder and tablet forms (cyclamate calcium). Now available in food stores.

What makes Viceroy different from other filter cigarettes?

Only VICEROY— has 20,000 tiny filters in every tip . . . twice as many as the other two largest-selling filter brands! That's why you get that fresh, clean real tobacco taste!

TWICE AS MANY FILTERS

The VICEROY filter tip contains 20,000 tiny filters made exclusively from pure cellulose . . . soft, snow-white, natural. This is twice as many filters as the other two largest-selling filter brands.

That is why VICEROY gives you such a fresh, clean taste—that real tobacco taste you miss in other filter brands. No wonder so many doctors now smoke and recommend King-Size VICEROYS.

If it's Viceroy you can tell the difference blindfolded!

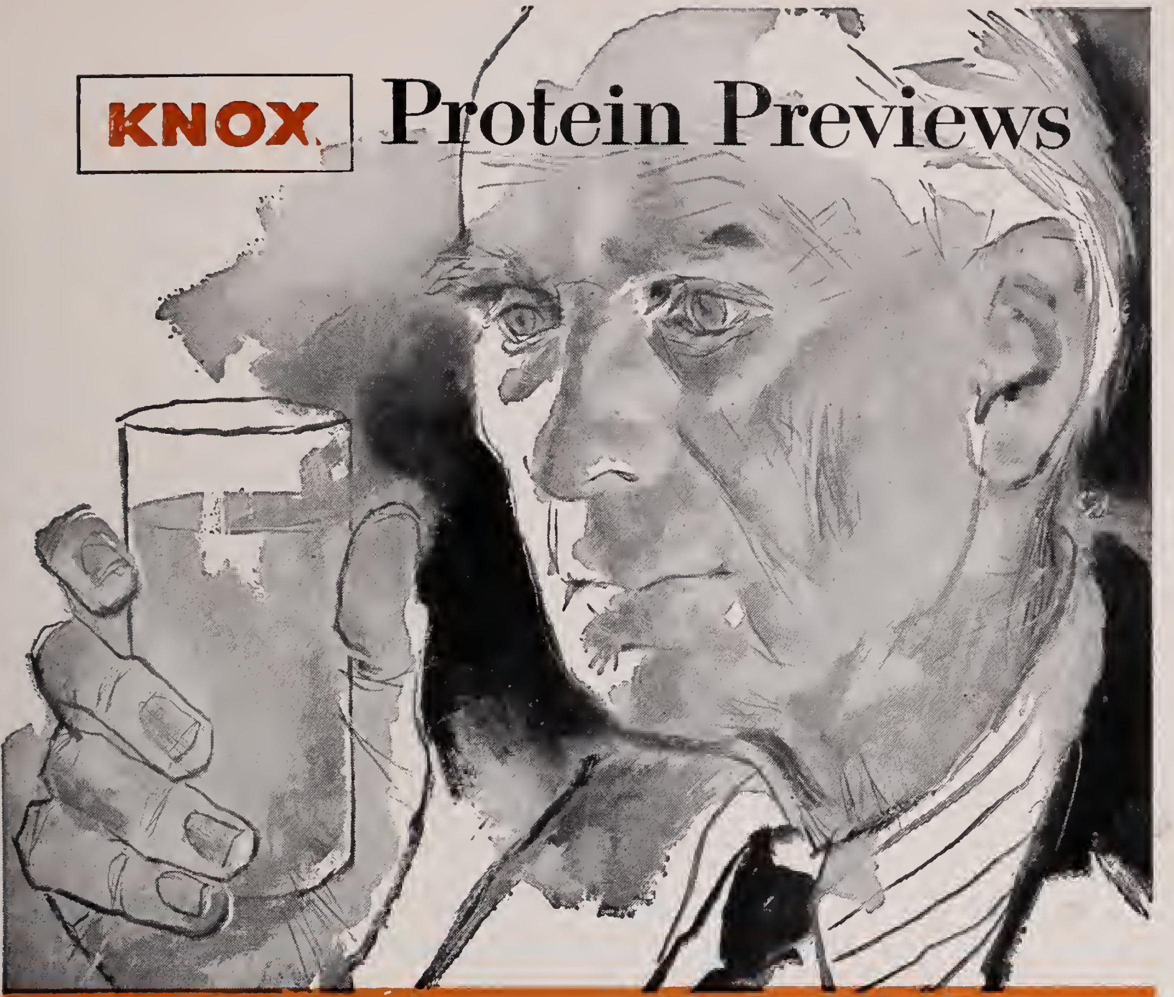
KNOX Protein Previews



Maintaining Lean Body Mass in the Edentulous Geriatric Patient

KNOX
32
UNFLAVORED
GELATINE

Extensive loss of body protein can occur in either the spare or obese geriatric patient. But whatever the patient's somatotype, a decrease in lean body mass is usually the result of inadequate protein intake due to poor dentition, slowed-down digestion and quite frequently, unappetizing main dishes.

Knox Gelatine is an excellent non-residue protein which is easy to chew and readily digested and assimilated. As a vehicle for many foods, Knox Gelatine brightens bland diets, giving a new interest to jaded appetites. As a concentrated protein drink, Knox Gelatine supplies seven out of eight essential amino acids and a majority of the other amino acids composing protein.

Specific suggestions on how to use Knox Gelatine in different types of geriatric diets are described in the booklets listed in the coupon below.

Chas. B. Knox Gelatine Company, Inc.

Why Gantrisin?

... because this single sulfonamide is so soluble -- even in acid urine -- that it is not likely to endanger normal kidney function; because it has a wide antibacterial spectrum; and because it does not, as a rule, cause gastrointestinal upsets or overgrowth of fungi. Patients usually respond so satisfactorily that it has become ...

a sulfonamide of first choice

Gantrisin® - brand of sulfisoxazole

The judge

of an antibacterial is the physician. Your decision will be based on effectiveness and safety. Gantrisin (acetyl) Pediatric Suspension is effective against a wide range of pathogens; because Gantrisin is highly soluble there is little danger of renal damage and no need for alkalies.

The jury

... your younger patients especially ... will render a verdict on taste. Gantrisin (acetyl) Pediatric Suspension is popular with children for its delicious raspberry flavor.

Gantrisin® - brand of sulfisoxazole
Gantrisin® acetyl - brand of acetyl sulfisoxazole

Meat...

and the Value of Fat in Nutrition

Authorities in the field of nutrition no longer consider fat as an optional component of the diet. Evidence from the laboratory and bedside indicates that fat in small amounts may be looked upon as an obligatory constituent of a health-promoting diet.[1]

The far-reaching value of fat in nutrition has been amply demonstrated in laboratory animals in its pronounced effect on growth, on pregnancy and lactation, on nitrogen-sparing action, on work capacity, on time of sexual maturity, on the period of survival during fasting, and on ability to combat external stresses.[1]

Young animals fed a fat-free diet not only fail to grow normally, but develop hair and skin changes characteristic of "essential" fatty acid deficiency.[2] Fatty acids other than the "essential" fatty acids also appear to be necessary for optimal health. Animals fed "essential" fatty acids but no others do not grow optimally.

The value of fat in human nutrition was emphasized in a recent study[2] comprising 200 patients incapable of receiving adequate nourishment. For periods of 1 to 30 days, these patients were given supplementary fat alimentation by vein in the form of fat emulsion containing "essential" as well as other fatty acids. The result was typically a marked increase in weight and more positive nitrogen and potassium balances.

Meat, recognized for its high content of biologically valuable protein, B vitamins, and essential minerals, provides, in addition, substantial amounts of nutritionally important fat.

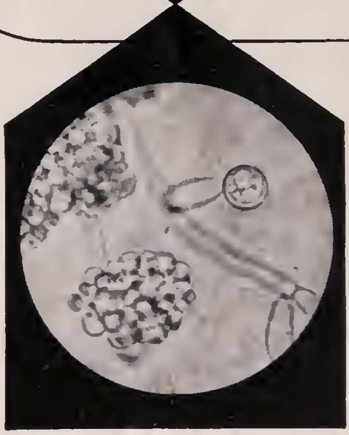
the only broad spectrum antibiotic preparation that...

1 provides the antimicrobial activity of tetracycline

Because it contains Steclin (Squibb Tetracycline), the well tolerated broad spectrum antibiotic, MYSTECLIN is an effective therapeutic agent for many common infections. Most pathogenic bacteria, as well as certain large viruses, certain Rickettsiae, and certain protozoans, are susceptible to Mysteclin.



2 protects the patient against monilial superinfection

Because it contains Mycostatin (Squibb Nystatin), the first safe antifungal antibiotic, MYSTECLIN acts to prevent monilial overgrowth frequently observed during broad spectrum antibiotic therapy. Manifestations of this overgrowth may include some of the diarrhea and anal pruritus associated with antibiotic therapy, as well as vaginal moniliasis and thrush. On occasion, serious and even fatal infections caused by monilia may occur.

Mysteclin

STECLIN-MYCOSTATIN
(Squibb Tetracycline–Nystatin)

Each MYSTECLIN Capsule contains 250 mg. Steclin (Squibb Tetracycline) Hydrochloride and 250,000 units Mycostatin (Squibb Nystatin).

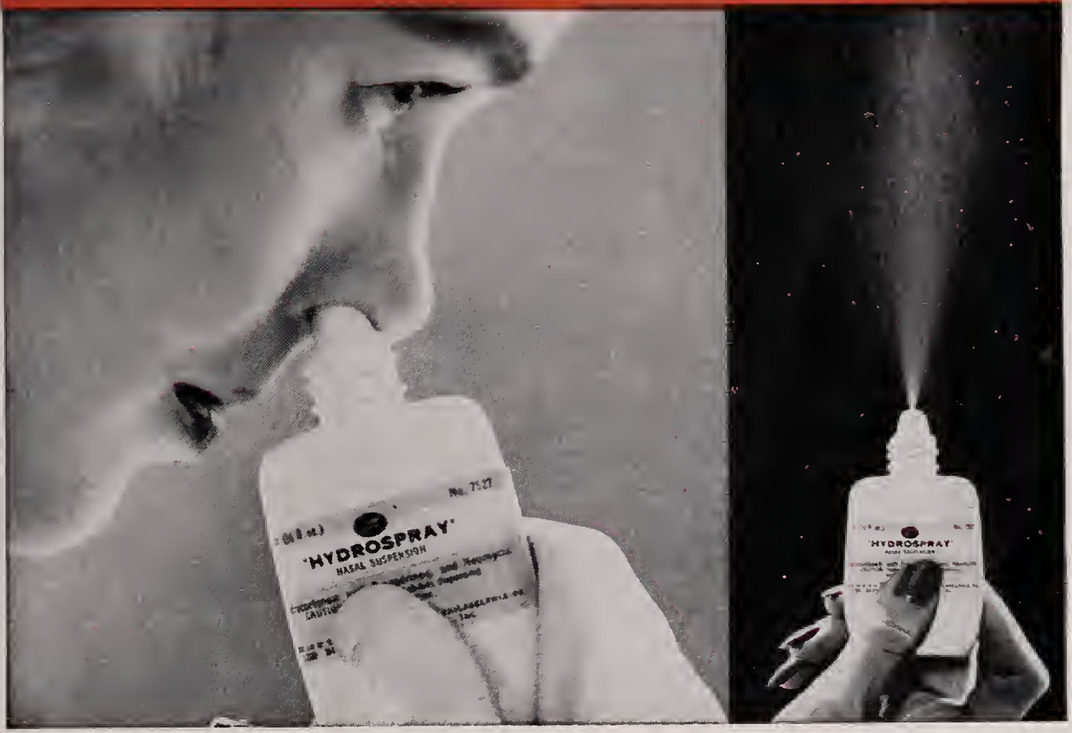
'Hydrospray' NASAL SUSPENSION

(HYDROCORTONE® WITH PROPADRINE® AND NEOMYCIN)

Anti-inflammatory—
Decongestant—Antibacterial

MAJOR ADVANTAGES: New synergistic anti-inflammatory, decongestant and antibacterial formula. High steroid content assures effective response.



Topically applied hydrocortisone[1] in therapeutic concentrations has been shown to afford a significant degree of subjective and objective improvement in a high percentage of patients suffering from various types of rhinitis. HYDROSPRAY provides HYDROCORTONE in a concentration of 0.1% plus a safe but potent decongestant, PROPADRINE, and a wide-spectrum antibiotic, Neomycin, with low sensitization potential. This combination provides a three-fold attack on the physiologic and pathologic manifestations of nasal allergies which results in a degree of relief that is often greater and achieved faster than when any one of these agents is employed alone.
INDICATIONS: Acute and chronic rhinitis, vasomotor rhinitis, perennial rhinitis and polyposis.

SUPPLIED: In squeezable plastic spray bottles containing 15 cc. HYDROSPRAY, each cc. supplying 1 mg. of HYDROCORTONE, 15 mg. of PROPADRINE Hydrochloride and 5 mg. of Neomycin Sulfate (equivalent to 3.5 mg. of neomycin base).

Re-activate the arthritic

Sterane

MOST POTENT ANTI-RHEUMATIC*

Even where hydrocortisone, cortisone, and other agents had failed, prednisolone (STERANE) restored articular mobility and functional capacity to normal in rheumatoid arthritis.[1]

Four times more effective than hydrocortisone, and, on the basis of preliminary findings,[2,3] superior in potency even to prednisone (cortisone analog), STERANE is also relatively free of such hormonal side effects as edema, hypertension, or hypopotassemia.

Supplied: White, 5 mg. oral tablets, in bottles of 20 and 100. Pink, 1 mg. oral tablets, in bottles of 100. Both are deep-scored and in the distinctive "easy-to-break" size and Pfizer oval shape.

The Importance of the Pulmonary Nodule

DONALD L. PAULSON, M.D.
Dallas, Texas

THE importance of the pulmonary nodule has begun to be appreciated only recently in spite of numerous papers which have been published on the subject since 1936. The frequency with which pulmonary nodules are discovered is in direct proportion to the use of routine roentgenograms of the chest. In recent years an active interest in the significance of the pulmonary nodule has been stimulated by an increasing frequency of discovery of these lesions, the realization of their malignant possibilities in a high percentage of cases, and advances in anesthetic and thoracic surgical techniques.

The term pulmonary nodule as used here refers to a single nodular lesion within the lung substance, usually less than 6 cm. in diameter, and surrounded by normal appearing lung tissue on all sides. Hilar, mediastinal, chest wall, and superior sulcus masses are excluded, as are the extremely small or large masses, all of which present a different problem. A pulmonary nodule may or may not produce symptoms. It need not be of homogenous density and may contain calcium. In a broad sense its shape is roughly round or oval, but its border may be notched or nodular, and is not always sharply circumscribed. These nodules have been referred to as coin lesions, solitary round lesions, solitary circumscribed lesions, solitary intrapulmonary tumors, isolated intrathoracic nodules, and single circumscribed intrathoracic densities. There are objections to all of these terms, as pointed out by Sharp and Kinsella[1] and by Fink[2] on the basis of inaccuracy of description. The term pulmonary nodule as herein defined is believed to be more appropriate, as it is a simple anatomic description of a single pulmonary lesion usually of undetermined etiology clinically.

Although Graham and Singer[3] as long ago as 1936 and Alexander[4] in 1942 advocated thoracotomy as the only reliable means of establishing a diagnosis for a circumscribed pulmonary lesion, there are those who do not appreciate the reasons therefor and mistakenly believe that these lesions are usually benign. That this view is still widely prevalent in the medical profession is the stimulus for this paper. Only by careful study of the material available and the widespread dissemination of the results will erroneous beliefs be disavowed. Those skilled in the treatment of chest diseases are in almost complete agreement on the need for prompt exploratory thoracotomy as a diagnostic as well as a therapeutic procedure for the indeterminate pulmonary nodule. That there is not such universal agreement among the general medical profession and the lay public constitutes a challenge of education for those of us well versed in diseases of the chest.

Review of the Literature

From a review of the literature it becomes clear that although the incidence of malignancy varies in individual reported series of pulmonary nodules from 7 per cent to 55 per cent, a significant number are cancers. The average incidence of malignancy for 897 cases is 36 per cent (Table I). It is important to realize that no one series is comparable to another because each series is selective on the basis of age, symptoms, size of the lesion, and the source of patients.

The reports of Jones and Cleve,[5] Effler, Blades and Marks,[6] Grow, Bradford and Mahon,[7] and Storey, Grant and Rothman[8] dealt in the main with young healthy adult males on active duty in the Armed Forces. Yet the incidence of malignancy ranged from 7 to 24 per cent. The patients in the series of Davis and Klepser,[10] O'Brien, Tuttle and Ferkaney,[12] Harrington,[15] Hood, Good, Clagett

TOTAL	897	323	36.0

and McDonald[17] were unselected with respect to age, and the incidence of cancer varied from 35 to 55 per cent.

The presence of symptoms has a definite effect on the incidence of malignancy. Some authors include only asymptomatic lesions and others all types of lesions regardless of symptoms. In the latter group, notably the reports of Davis and Klepser.[10] and O'Brien, Tuttle and Ferkany,[12] the cancer rates were higher, 55 per cent to 42.9 per cent, respectively. Symptoms were present in 76 per cent of the patients with a malignant tumor and in 23 per cent of those in whom the mass proved to be benign in Davis and Klepser's series.

The size of the lesion is also a selective factor. Sharp and Kinsella[1] limited their study to pulmonary nodules 1 to 4 centimeters in diameter and found malignancy in 27 per cent. It is obvious that larger pulmonary masses are more apt to be malignant. Thornton, Adams and Bloch[19] found an incidence of malignancy of 78.3 per cent of twenty-three patients having huge pulmonary masses.

The source of patients will have a natural selective effect in any series of pulmonary nodules. Reports emanating from facilities devoted particularly to the treatment of pulmonary tuberculosis would be expected to include a higher percentage of granulomas and consequently a lower incidence of cancer. Similarly, a thoracic surgeon reporting only his surgically proven lesions will find his series weighted in favor of carcinoma, because patients referred to him for surgery frequently will be those in whom cancer is suspected.

Material and Method of Study

The present series include 180 patients having pulmonary nodules seen by my associate, Dr. Robert R. Shaw, and me in the private practice of thoracic surgery from 1945 to 1955, a period of ten years. All patients seen by us meeting the definition of a pulmonary nodule were included regardless of age, symptomatology, or whether surgically proven or not. All factors of selectivity are interlinked, and the exclusion of an asymptomatic granuloma in a younger person because it is not surgically proven weights the series in favor of malignancy. It is for this reason that the surgically unproven as well as those proven by operation are included.

Of the total number of 180 patients with pulmonary nodules, 143 or 80 per cent were operated upon and the diagnosis proven pathologically. The remaining thirty-seven patients were not operated upon because surgery was contraindicated or refused or because a reliable diagnosis could be made on clinical grounds alone.

The pulmonary nodule could be classified on a clinical and roentgenographic basis in our opinion in the case of twenty-four patients or 13 per cent of the total number. Five of these patients presented incontrovertible evidence of malignancy either on first examination or as a result of evidence gained later. The lesions could not be classified in the remaining thirteen patients or 7 per cent of the total. These were patients in whom surgery was contraindicated or refused and sufficient clinical or roentgenographic evidence was present to warrant classification on this basis.

Results

The results of classification of 180 consecutive pulmonary nodules are tabulated in Table II.

TABLE III. DISTRIBUTION OF 180 PULMONARY NODULES ACCORDING TO AGE AND SEX OF THE PATIENTS

TOTAL	180	106	74	12	29	49	50	36	3	1	

It is significant that seventy-eight patients had a malignant nodule, an incidence of malignancy of 43 per cent. There were sixty-two bronchogenic carcinomas or 34 per cent, seven metastatic nodules or 4 per cent, and nine bronchial adenomas or 5 per cent of the total. Only ten patients or 6 per cent of the total 180 patients had true benign tumors.

An inflammatory nodule was present in seventy-four patients or 41 per cent of the total. Of these, sixty-seven or 37 per cent of the total were classified as granulomas. There were twenty-four tuberculomas, twelve coccidioidal granulomas, and thirty-one of undetermined etiology. Nineteen of the thirty-one nodules classified as granulomas of undetermined etiology were not proven pathologically. The age of the patient and the roentgenographic appearance of lamination, the presence of calcification, or surrounding halo justified this classification and surgery was unnecessary for corroboration.

Pneumonitis, abscess, or filled in cyst accounted for the pulmonary nodule in seven patients or 4 per cent of the total.

Miscellaneous lesions, including arteriovenous fistula, pulmonary infarction, pleural fibrosis, actinomycosis, and Hodgkins disease, accounted for five pulmonary nodules or 3 per cent of the total.

Thirteen pulmonary nodules or 7 per cent of the total could not be classified.

The age and sex distribution of the 180 patients is given in Table III. There were 106 men and seventy-four women. Men predominated over women in both the groups of bronchogenic carcinoma and granuloma. Women predominated over men in the groups of bronchial adenoma, pneumonitis, abscess, and cyst and the unclassified group. Men and women were about evenly divided in the benign tumor, metastatic nodule, and miscellaneous group.

The ages of these 180 patients ranged from six to eighty-one years. The six-year-old patient was a girl who has survived and is well eight years following the removal of a metastatic nodule secondary to a Wilm's tumor of the kidney. The age distribution of the bronchogenic carcinoma group was from thirty-six to seventy-nine years, predominating in the fifth, sixth and seventh decades. The thirty-six-year-old patient was a woman whose pulmonary nodule was due to an adenocarcinoma which was watched and treated with streptomycin for ten months because she had some healed scars in the contralateral lung. There were no bronchogenic carcinomas below the age of thirty-five years.

The age distribution of the granuloma group varied from twenty-three to sixty-six years, the larger groups being in the fourth, fifth and sixth decades but extending into the third and seventh decades.

The remaining groups were small and evenly distributed as to age.

The incidence of malignancy increases from 43 per cent in the fifth decade to 64 per cent in the seventh decade. Seven malignant nodules were found in 41 patients under the age of forty years, an incidence of 17 per cent. The age of

TOTAL	63	66	13	2

thirty-five years seems to be a more reasonable dividing line as far as bronchogenic carcinoma is concerned because none of these occurred below this age. The occurrence of bronchogenic carcinoma in a pulmonary nodule below the age of thirty-five years is possible but very rare. Other malignant nodules, a bronchial adenoma and metastatic nodules, occurred in three patients below the age of thirty-five years.

Statistically the granulomas predominate below the age of thirty-five years, but may be found in any age group even in the seventh decade.

Symptoms of pain, hemoptysis, cough or fever were present in forty-one of sixty-two patients having bronchogenic carcinoma or 69 per cent, and twenty-seven of sixty-seven patients in the granuloma group or 40 per cent. Four of the patients in the granuloma group had hemoptysis.

Inasmuch as symptoms were not present in 30 per cent of the patients with bronchogenic carcinoma, an asymptomatic lesion cannot even be remotely considered as benign. As a matter of fact, much of the early detection and the improvement of the results of surgical removal of carcinoma depend on finding the malignant nodule in an early silent phase.

One hundred forty-four operative procedures were done for 180 pulmonary nodules. There was no surgical mortality. Careful attention to the principal of preservation of lung tissue is evidenced by the fact that segmental resection was possible in sixty-three patients, including six with bronchogenic carcinoma, one with a metastatic nodule, and two with bronchial adenoma. Eight of the ten benign tumors were removed by segmental resection, as were forty-four of the fifty-four inflammatory lesions, including all but seven of the granuloma group. Lobectomy was necessary for fifty-three of the malignant tumors and ten of the inflammatory group. Thirteen pneumonectomies and two exploratory thoracotomies were done, all in the group of malignant nodules (Table IV).

TABLE V. SURVIVAL FOLLOWING RESECTION OF 37 SYMPTOMATIC PULMONARY NODULES DUE TO BRONCHOGENIC CARCINOMA

Less than 1 year	13	12	82
1 year	9	6	
2 years	2	2	40
3 years	3	0	
4 years	4	1	
5 years or more	6	3	
TOTAL	37	24	65

Justifiable criticism was made recently by Hodgson[20] of the lack of follow-up studies concerning patients with malignant pulmonary nodules for which resection had been performed. The data to date concerning the survival rates of fifty-six patients whose bronchogenic carcinoma presenting as a pulmonary nodule was resected are presented in Tables V and VI. The patients were divided according to the presence or absence of symptoms because theoretically the latter group should have a better survival rate.

Resections were done in thirty-seven patients in the group of pulmonary nodules due to bronchogenic carcinoma with symptoms. There were no hospital mortalities. Twenty-four of the thirty-seven patients or 65 per cent have survived. Six of the fifteen patients whose carcinoma was resected over two years ago are alive, a survival rate of 40 per cent for this period. Three of the six patients whose carcinoma was resected over five years ago are alive five, six and ten years, respectively.

Resections were done in nineteen patients hav ng a pulmonary nodule caused by bronchogenic arcinoma without symptoms. There were no urgical mortalities. Fifteen or 80 per cent of hese nineteen patients have survived. Seven of the en patients whose resection was done two or more ears ago are alive, a survival rate of 70 per cent or this period.

The combination of the results of resection for oth the symptomatic and asymptomatic group of ulmonary nodules due to bronchogenic carcinoma reveals thirteen or twenty-five patients alive r a 50 per cent survival rate for resections done ver two years ago (Table VII). Enough time has not elapsed to evaluate five-year survival rates in a significant number of patients. Six of fourteen patients operated upon four or more years ago are alive, a survival rate of 43 per cent for this period.

TABLE VI. SURVIVAL FOLLOWING RESECTION OF 19 ASYMPTOMATIC PULMONARY NODULES DUE TO BRONCHOGENIC CARCINOMA

PERIOD SINCE RESECTION	NUMBER OF RESECTIONS	NUMBER ALIVE	PERCENT SURVIVING
Less than I year	7	6	90

4 years	3	2	
5 years or more	I	0	
TOTAL	19	15	79

It would appear from the statistics available that resection for the malignant nodule due to bronchogenic carcinoma yields a satisfactory survival for periods over two years at least.

Discussion

The importance of the pulmonary nodule lies in the fact that a high percentage of these lesions are malignant, in this series 43 per cent. The surgical mortality for resection of the pulmonary nodule is very low, and the results of resection for those nodules due to bronchogenic carcinoma indicate a satisfactory long-term survival rate. The general policy of prompt exploratory thoracotomy for diagnosis as well as the treatment of an indeterminate pulmonary nodule is on a sound basis. The burden of proof in the individual case is on the shoulders of the person who says a particular lesion is benign and does not require surgical removal for diagnosis and treatment.

TABLE VII. SURVIVAL RATE FOR THE ENTIRE GROUP OF PULMONARY NODULES DUE TO BRONCHOGENIC CARCINOMA WITH OR WITHOUT SYMPTOMS

PERIOD SINCE RESECTION	NUMBER OF PATIENTS	NUMBER ALIVE	PERCENT SURVIVING
Less than I year	20	18	84
I year	11	8	
2 years	7	6	50
3 years	4	I	
4 years	7	3	
5 years or more	7	3	
TOTAL	56	39	70

There is good reason for further attempts to outline diagnostic criteria which may be used justifiably to delineate the individual problem. In general, the age of the patient and certain roentgenographic and laboratory information may be of assistance.

Age

In this series of pulmonary nodules there were only three malignant nodules in persons below the age of thirty-five, two metastatic nodules and one adenoma. There were no bronchogenic carcinomas in persons under thirty-five. In this same age group there were sixteen granulomas. It would appear safe to say that below the age of thirty-five years a pulmonary nodule has an overwhelming chance of being a granuloma, and that if it is malignant, it will be metastatic or an adenoma. Bronchogenic carcinoma begins to appear in the age from thirty-five to forty years and beyond this age the incidence of malignancy increases from 43 per cent in the fifth decade to 64 per cent in the seventh decade.

Roentgenographic Criteria

The size and density of the lesion may be of significance, relatively speaking. Vivas and Crabtree[21] found that lesions of medium and small size of light density should be considered malignant (Fig. 1), that lesions of medium and small size of medium density should be studied carefully, and that lesions of heavy density are not likely to be malignant. The larger lesions are more likely to be malignant, although mesotheliomas and hamartomas may attain large size before being found (Fig. 2).

Rigler[22] has called attention to a new sign of malignancy of the pulmonary nodule, consisting of notching or umbilication of a border of the shadow (Fig. 3). It would appear that this sign is of relative value, being significant by its presence but not by its absence. It may be produced by other lesions, particularly by a coccidioidal glanuloma.

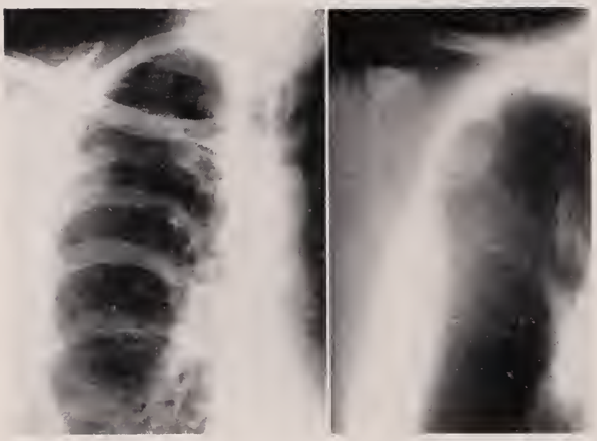

Fig. 1. Pulmonary nodule of medium size and light density in the right lung. Plain roentgenogram and planigram. Proven bronchogenic carcinoma.

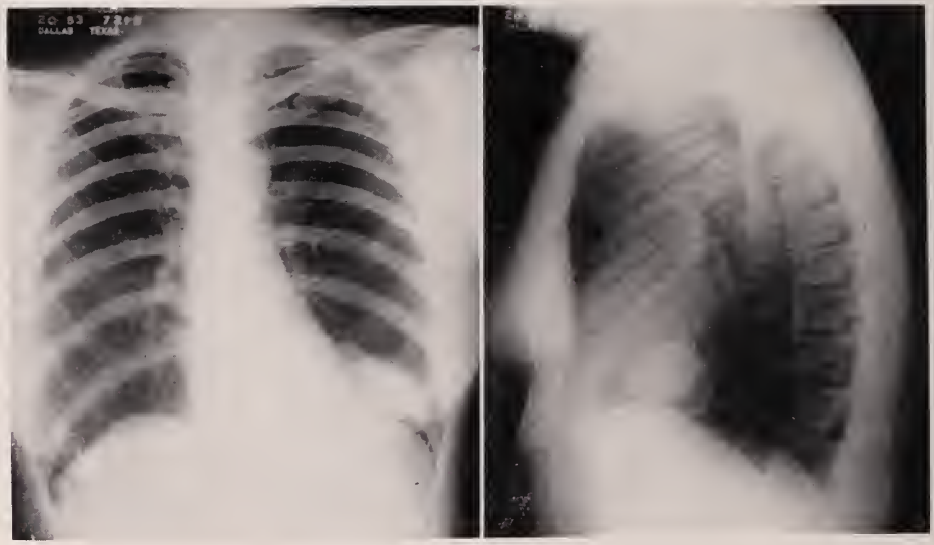

Fig. 2. Mesothelioma, aysmptomatic, found on roentgenogram made in survey.

Lamination, calcification or a surrounding halo all are in favor of the diagnosis of a granuloma or a benign lesion. Planigraphic films are necessary for proper evaluation and one must be sure that what is seen in the roentgenogram is truly calcium and that it does lie in the mass (Fig. 4). Bloch[23] has shown that the degree of calcification in the roentgenogram is arbitrary and dependent on special techniques for demonstration. The Mayo Clinic group[17] found calcification by planigraphic techniques in the benign nodules only. On the other hand, Tuttle,[24] May, Rose and Dugan,[18] and Hodes[25] report several cases in which nodules containing calcium proved to be malignant. We have seen a similar patient in whom surgery was deferred because of apparent calcification within a pulmonary nodule, to be embarrassed by return of the patient at a later date with cerebral metastases from the adenocarcinoma responsible for the nodule. It would appear that the presence of calcium favors benignancy but at best is a relative criterion and is not sufficient evidence alone to prevent the patient from having the benefits of removal of the lesion and histologic examination.

From a diagnostic standpoint, the presence of calcium on roentgenographic examination does not warrant unlimited assurance. Some lesions, such as granulomas, with a high calcium content may be soft and caseous and therefore capable of progression and spread. Multiple areas of rarification within a granulomatous process may represent areas of activity and thus contraindicate delay. Calcification should probably be considered safe only if it occurs in a solid, uniform manner.

Previous chest films may be of importance in demonstrating the lesion to be of long standing and hence less likely to be malignant. However, several cases of malignant nodules are on record that have been present unchanged for a period of years.

Limitations of Laboratory Procedures

Many laboratory procedures are available for the study of pulmonary nodules, but availability alone does not justify prolonged and expensive preoperative examinations of the patient. The peripheral location of the pulmonary nodule makes most important available diagnostic aids ineffective.

Bronchoscopy is seldom indicated or justified in a patient with a pulmonary nodule unless he has symptoms suggestive of an associated bronchial lesion. Cytologic examination of the sputum or bronchial secretions for malignant cells is of value only if a positive result is obtained. A negative examination does not rule out malignancy. For the most part, a pulmonary nodule is unfavorably located for the exfoliation of malignant cells.

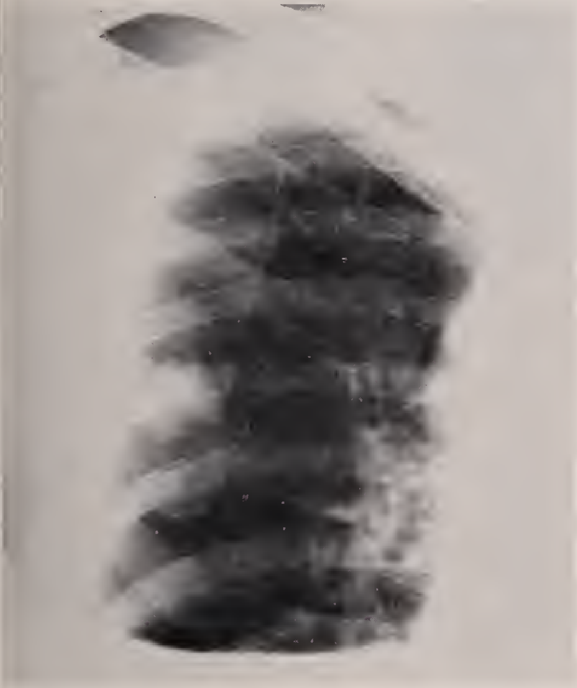

Fig. 3. Notching or umbilication of a border of a pulmonary nodule due to bronchogenic carcinoma.

Skin tests to determine the patient's sensitivity to tuberculin, histoplasmin or coccidioidin are at best inconclusive regarding the precise nature of the nodule. A positive reaction does not indicate that the nodule in question is responsible (Fig. 5). A series of negative reactions increases the suspicion of neoplasm. Some patients with a negative reaction may have a granuloma.

The sedimentation rate is frequently elevated in patients with malignant lesions but usually not in those with benign lesions. There is little justification for bacteriologic examination of the sputum of a patient with a solitary pulmonary nodule. Certainly there is no justification for waiting weeks for the results of a culture.

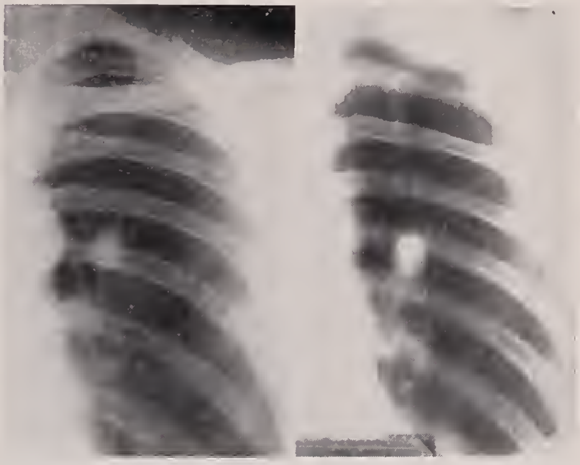

Fig. 4. Plain roentgenogram and planigram revealing calcium in a pulmonary nodule.

We believe that proper evaluation of a patient with a pulmonary nodule consists almost entirely of the use of roentgenographic techniques to include planigraphic films, survey of the patient from a general standpoint, and unless contraindicated, prompt surgical removal and histologic examination. The age of the patient and the roentgenographic appearance justified referring surgery in only 13 per cent of the patients in this series.

Metastatic Nodules

Knowledge of a malignancy elsewhere in the body or the history of a previously removed cancer is suggestive evidence of the metastatic nature of a pulmonary nodule but is by no means conclusive. Multiple primary cancers in unrelated systems can and probably will occur more frequently as survival rates improve. The appearance of a pulmonary nodule in a patient with a known cancer primary in another site may indicate the presence of a new primary cancer of the lung. Cahan[26] has reported only eighteen solitary metastases in the lungs during a period when 64 separate primary cancers of the lung were found at Memorial Hospital in patients with cancer at another site. This indicates a 3½ to 1 chance that a solitary pulmonary shadow is a separate primary lung cancer rather than a solitary metastasis in Memorial Hospital. One patient in our series has survived ten years following the removal by segmental resection of a primary adenocarcinoma of the lung occurring five years after the treatment of an epidermoid carcinoma of the cervix.

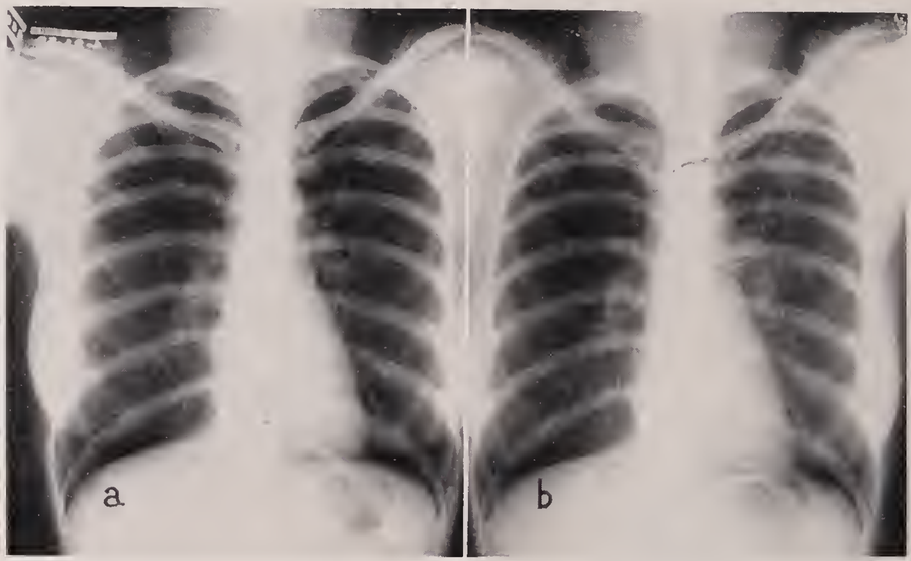

Fig. 5. (a) Pulmonary nodule, left upper lobe, interpreted as due to tuberculosis because of a positive tuberculin skin test and old scars in the contralateral lung.
(b) The same nodule ten months later, increased in size. Pneumonectomy was necessary at this time for an adenocarcinoma with extensive hilar and mediastinal metastases.

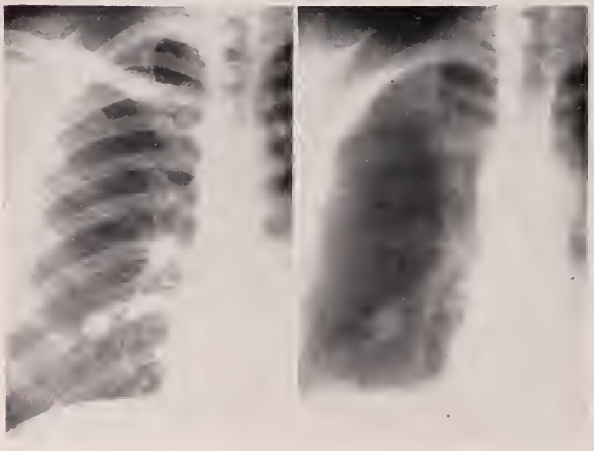

Fig. 6. Plain roentgenogram and planigram revealing pulmonary nodule in right lower lobe. Known seminoma of the testis. Excision of the nodule proved to be a hamartoma.

A benign tumor or a granuloma may likewise account for a pulmonary nodule in a patient with a known primary cancer in another site. Illustrative of this fact is the case of a thirty-six-year-old man who was found to have a pulmonary nodule shortly after the removal of a seminoma of the testis (Fig. 6). The nodule was removed and proved to be a hamartoma.

Synchronous cancers may occur in different organs and need not contraindicate surgery. In general, the more malignant lesion should be treated first. In most cases this will be the pulmonary lesion.

The mere presence of a pulmonary nodule does not justify exhaustive examinations in a blind search for a primary malignancy without any other indication that such a lesion is present. The removal of the pulmonary nodule alone will establish its true nature and if metastatic, frequently indicates the site of the primary tumor.

Those persons thought to have a metastatic pulmonary nodule should have planigraphic roentgen examinations done because multiple nodules may not be apparent in roentgenograms done by the usual techniques.

Granulomas

The resection of a pulmonary nodule due to granuloma is most often advised because it is often indistinguishable from a malignant nodule. This is true of all types due to tuberculosis, histoplasmosis, and coccidiodomycosis, particularly the last (Fig. 7).

One may also justify the resection of granulomas on the basis that these lesions are potentially dangerous from the standpoint of progression. Mitchell[27] has shown that after prolonged observation, there is about one chance in four of progression of disease when pulmonary tuberculosis is characterized by solitary dense circumscribed foci (tuberculomas) and has been treated without chemotherapy, resection or permanent collapse. Mathers[28] made a similar observation concerning twenty-three tuberculomas observed for from five to ninety months. Three tuberculomas cavitated with bronchogenic spread, four cavitated only, and five enlarged.

Matthiesen[29] has called attention to the surgical significance of solitary circumscribed lung nodules in histoplasmosis and states that surgical resection of pulmonary lesions is good treatment in the management of such localized histoplasmosis infections.

Summary

1. The importance of the pulmonary nodule lies in the fact that of 897 cases collected from the literature, 323 or 36 per cent were malignant.

2. The author's series of 180 patients having pulmonary nodules and ranging in age from six to eighty-one years has been reviewed. Eighty per cent of these patients were operated upon and the diagnosis proven pathologically. There were no surgical mortalities. The diagnosis could be made reliably on a clinical and roentgenographic basis in 13 per cent, and the lesions could not be classified in the remaining 7 per cent.

3. There were sixty-two patients with bronchogenic carcinoma or 34 per cent, seven with metastatic nodules or 4 per cent, and nine with bronchial adenomas or 5 per cent of the total. Forty-three per cent were malignant nodules. Only ten patients or 6 per cent of the total had true benign tumors.

4. The pulmonary nodule was produced by inflammation in seventy-four patients or 41 per cent of the total. Sixty-seven or 37 per cent of the total were classified as granulomas.

5. The age distribution revealed seven malignant nodules in forty-one patients under the age of forty years, an incidence of seventeen per cent. There were no bronchogenic carcinomas below the age of thirty-five years although there were two metastatic nodules and one adenoma below this age. The incidence of malignancy increases from 43 per cent in the fifth decade to 64 per cent in the seventh decade.

6. The results of resection for pulmonary nodules due to bronchogenic carcinoma indicate a 40 per cent survival rate for two years or more for the lesion with symptoms and a 70 per cent survival rate for the same period for the same lesion without symptoms.

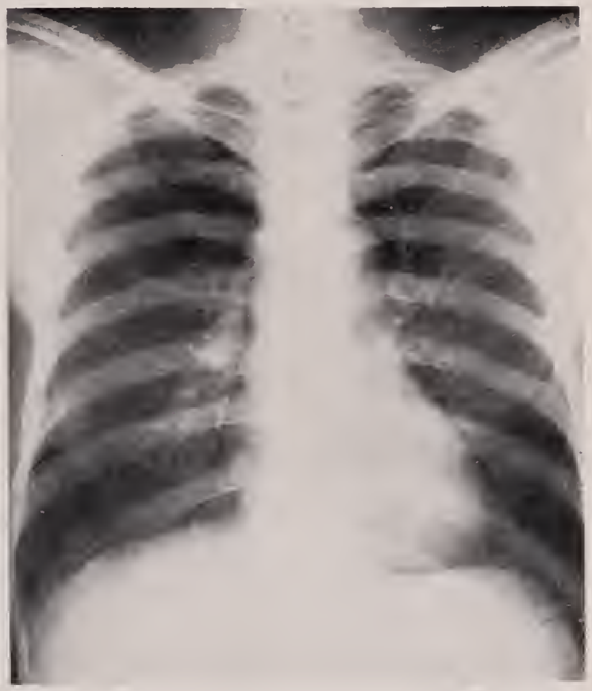

Fig. 7. Pulmonary nodule of medium size and soft density. Excision and examination revealed a coccidioidal granuloma.

7. The policy in general of prompt exploratory thoracotomy for the diagnosis and treatment of an indeterminate pulmonary nodule is on a sound basis.

8. The proper evaluation of a patient with a pulmonary nodule consists of the use of roentgenographic techniques to include planigraphic films, survey of the patient from a general standpoint, and unless contraindicated, prompt surgical removal and histologic examination. Extensive laboratory examinations are unjustified as inconclusive.

9. Resection of an apparent metastatic malignant nodule should be considered because of the possibility of the lesion being a separate primary lung cancer or a benign lesion, as well as for the opportunity of longer survival following the removal of a known metastasis.

them; the lower sphincter is formed by the true vocal cords and the muscles which adduct them.

The laryngeal ventricles are "alcoves" located to the side of the main laryngeal cavity. They open into the laryngeal airway between the upper and lower sphincters. The sacculus of the larynx is a small pouch connected to the superior portion of the ventricle. In activity requiring glottic closure, the air pressure may be transmitted to the ventricle and saccule because the true cord sphincter is weaker than the false cord sphincter; as the pressure in the tracheo-bronchial tree increases the lower laryngeal sphincter may be forced open. The laryngeal ventricle and saccule can then be distended.

Some activities involve general increase in pressure throughout the airway but do not entail glottic closure of the degree just described. These include sneezing, nose blowing, coughing, glass blowing and the playing of certain wind instruments.

Perhaps the presence of a congenital sac attached to the side of the laryngeal airway plus a force to distend that sac are necessary to the formation of a laryngocele. The experiments of Monselles,[11,12] (Florence) in 1900 seem to support such a view. He attempted to produce eversion of the ventricle artificially in thirty-three cases after death without success. In every case the mucous membrane instead of the submucosa was torn on attempting to draw out the lining of the ventricle.

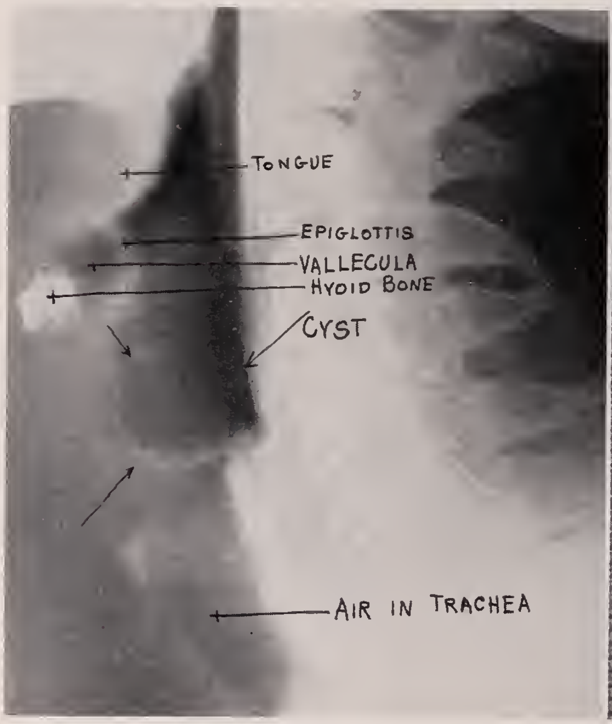

Fig. 2. (Case 1) Lateral view of the soft tissues of the neck showing air-filled cyst lying between the upper end of the larynx and the hyoid bone and projecting into the air-filled pharynx.

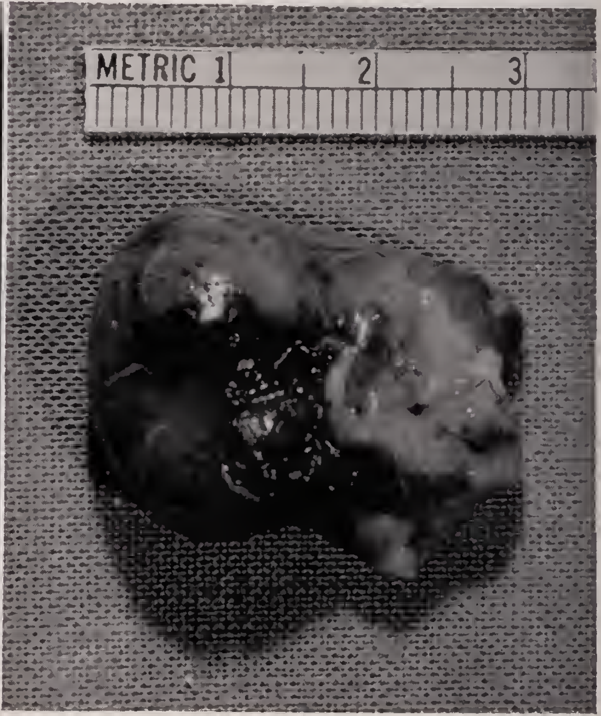

Fig. 3. (Case 1) Photograph of surgical specimen from Case 1 showing the air-filled sac, still intact, after removal from the patient's neck.

Laryngocele in man is divided into three classes by Lindsay[13] and by Allmans and Cordray.[14]

1. Internal laryngocele—a cystic dilatation within the larynx above the false cord extending to the aryepiglottic fold or base of the tongue (Freu). The cyst dilates on forced expiration; it deflates on quiet respiration. Hoarseness accompanies dilatation of the sac (see Case 1).

2. Superior external laryngocele—a cystic dilatation of the saccule of the ventricle that penetrates the thyrohyoid membrane just above the superior rim of the thyroid cartilage and anterior to the superior cornu, or just lateral to the thyroid notch. It appears as a swelling of the neck and enlarges on cough and exertion. It can be emptied by external pressure. Distention of the sac produces discomfort and headache due to pressure on the large veins of the neck. Infection and accumula-

tion of fluid in the sac is likely to produce coughing and expectoration of pus when the sac is compressed.

3. A combination of (1) and (2); (see Case 2).
4. A fourth type has been described as inferior external laryngocele, but verification of this type by dissection or operation appears to be lacking.

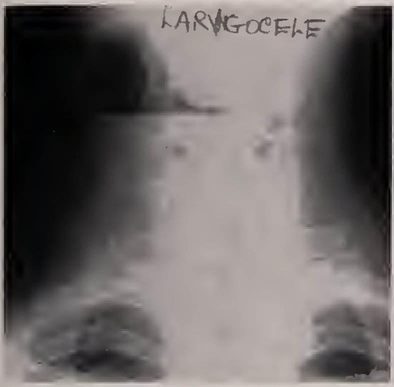

Fig. 4. (Case 2) Anteroposterior view of soft tissues of the neck showing laryngocele on the right side. The upper portion of the sac is filled with air and the lower portion with fluid. The fluid is forced into the airway by movements of the neck causing cough.

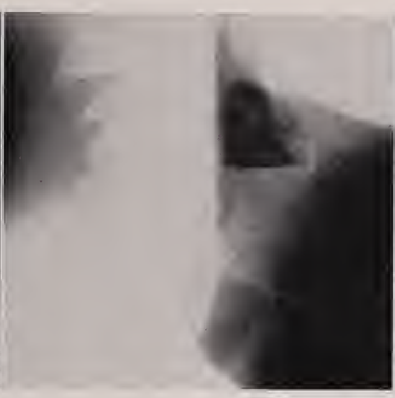

Fig. 5. (Case 2) Lateral view showing the same structures as described in Figure 4.

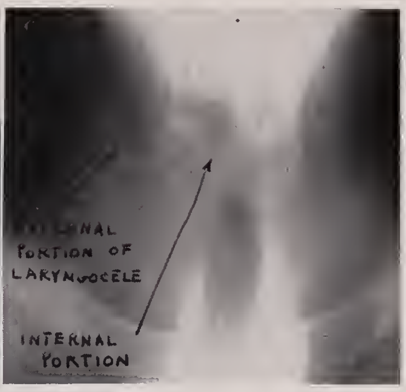

Fig. 6. (Case 2) Planogram of the neck in a posteroanterior view showing the combined internal and external laryngocele. As contrasted to the plain film shown in Figure 4, Figure 6 shows the inferior limits sac.

The symptoms of laryngocele will be noted in the reports of our cases. Cases 1 and 3 are examples of the internal type, while Case 2 is a combination of the internal and external types.

Case 1.—Mr. R. O. B., aged sixty-three years, was first examined by us in 1952. For the previous two months foods such as bread and meat had caught in his throat during swallowing. His wife said that he made a great noise when sleeping. This was not a typical snore but seemed to originate from a site in the lower pharynx. Other symptoms included hoarseness, cough, weight loss and marked sleepiness. The hoarseness grew worse as each day progressed, and the cough was non-productive but seemed to be due to irritation and not to excessive secretion within the respiratory tree. The man's weight had decreased 15 pounds in six months. There was no pain or dyspnea.

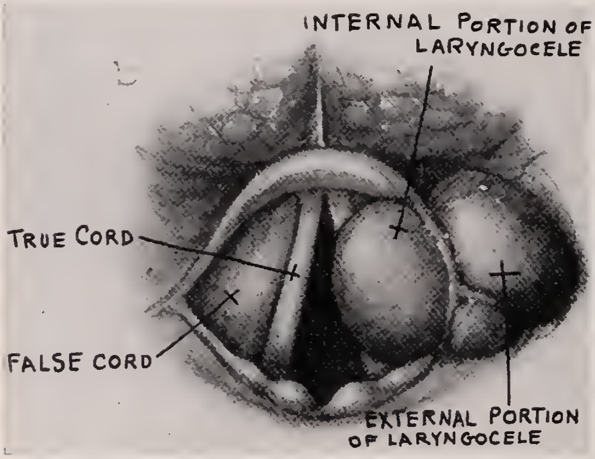
Indirect laryngoscopy revealed a large cyst on the right side of the larynx. It is interesting to note that the description of our case is the same as one described by Kistner in 1924.[10] He said, "Indirect inspection of the larynx revealed a large, smooth tumor obliterating the right aryepiglottic fold, bulging out toward the median line, obscuring any view of the right cord, ventricular band or arytenoid. The left arytenoid and its vocal process could be seen and were normal in appearance. The anterior two-thirds of the left cord could not be seen."

General physical examination showed no significant abnormality. In the ordinary films of the neck a rounded area of lessened density just above the right ventricular fold represented the laryngocele (Fig. 2). Planograms showed a large air-filled cyst filling the lumen of the larynx above the level of the ventricular folds and attached on the right. The possibility of an associated tumor was not excluded.

Tracheotomy under local anesthesia was carried out to assure patency of the airway during manipulation of the laryngeal cyst. When the incision was made into the trachea there was a sudden fall in blood pressure. Cocaine reaction or the curious syndrome exhibited by some patients having chronic hypoxia were considered as possible causes. Cocaine in a four per cent solution had been injected into the tracheal lumen a few minutes before opening the trachea. The patient's long standing sleepiness could have been due to chronic hypoxia. Nevertheless the removal of the laryngeal cyst was deferred for a few days.

Then a thyrotomy was done. The right ventricular fold was seen to be filled by a cystic mass. The soft tissues of the false cord were split along the cut edge and the mucosa peeled from the medial side of the cyst. The cyst was then shelled out carefully. The deep tissues of the ventricular band were separated from the thyroid cartilage and the cyst was delivered intact (Fig. 3). It contained air and floated in normal saline. The cyst was 2½ by 2½ by 3 cm. The wall was thin and on section the cyst was filled with air and mucus. The inner surface was smooth and was lined with normal appearing ciliated columnar epithelium. Within the wall of the cyst there were normal appearing mucus glands. The pathologist confirmed our diagnosis of laryngocele. The patient tolerated the procedure well and had an uneventful recovery.

Case 2.—Mr. C. L., aged thirty-six, complained of hoarseness of two months' duration and of a lump on the right side of his neck just above and lateral to the thyroid ala. His physician aspirated air and fluid from the mass in the neck. Subsequently he developed a secondary infection and fever. He responded to antibiotics but complained of a bitter discharge into his throat periodically. Planograms and plain posteroanterior and lateral x-rays of the larynx revealed a very large internal and external laryngopyocele partially filled with fluid and occupying the right side of the neck (Figs. 4, 5, 6). Indirect laryngoscopy showed a rounded mass protruding above the larynx at the level of the epiglottis (Fig. 7). The epiglottis was pushed sharply to the left.



INTERNAL PORTION OF LARYNGOCELE
TRUE CORD
FALSE CORD
EXTERNAL PORTION OF LARYNGOCELE

Fig. 7. (Case 2) Drawing of the view obtained with a mirror in Case 2 except that this figure shows a left-sided laryngocele, while our case was right sided. (From W. B. Hoover: Laryngocele. *Surgical Clinics of North America*. Philadelphia: W. B. Saunders, 1952.

At surgery a horizontal incision was made from the right sterno-mastoid muscle to the midline at the level of the hyoid bone. This was directly over the center of the mass. The skin, superficial fascia, platysma and deep fascia were divided. Under the deep fascia a cyst wall was visualized. It was picked up carefully and dissected out from its bed. The bed consisted of the hyoid bone and its attached muscles; the cyst passed the midline and at this time it was dissected off of the pharyngeal mucosa. It extended caudad for a distance of about 6 cm. and was dissected out until its attachments disappeared at its anterior medial end under the right ala of the thyroid cartilage just lateral to the thyroid notch. The entire structure at this point was not over 1.0 mm. in diameter. A midline incision extending from the thyroid notch down to the suprasternal notch was made. A tracheotomy was then done. The thyroid alae were separated from one another using an electric saw. On looking for the cut end of the sac it couldn't be found, but there was an opening in the midline at the point where the sac had been. This represented the retracted end of the sac where it attached to the patient's laryngeal ventricle. The opening was exactly opposite to the other laryngeal ventricle. The sac had already been completely removed, but we had not realized it and opened the larynx in the midline expecting to find the stub end of the cyst. The total volume of the sac was 120 cc. It was filled partially with a thick whitish fluid.

The cyst measured 5 by 3 by 2½ cm. The wall was thin and the lumen was filled with a cloudy mucus. Microscopic examination showed the cyst to be lined by respiratory tract epithelium. Beneath the epithelial lining were normal appearing mucus glands and evidence of recent hemorrhage into the fibrous connective tissue. The diagnosis was laryngocele. The patient tolerated the procedure well. For many months he had paralysis of his right vocal cord. This recovered completely.

It is not easy to believe that this man's cyst arose from forcible over-distention of a normal laryngeal ventricle. It must have been a congenital anomaly, probably a vestigial air-sac, and became distended when the tract connecting it to the larynx opened up, possibly due to coughing or straining.

Case 3. J. B. G., a seventy-four-year-old man, had slight hoarseness and was examined to rule out laryngeal cancer. The findings on physical and x-ray examinations were exactly like Case 1, but the cyst was small. This man had been observed from time to time for two years, and has no significant trouble. No surgery was necessary in this case. Laryngocele and cancer of the larynx have been reported in the same case by Schall.[16]

Summary

Three cases of laryngocele are presented, two of the internal type, the other a combination internal and external laryngocele. The history, anatomy, histology and etiology are reviewed.

Esophageal Hiatus Hernia

R. H. LA BREE, M.D.,
and J. FULLER, M.D.
Duluth, Minnesota

SINCE the subject of esophageal hiatus hernia is extensive, we propose to discuss only that type of diaphragmatic hernia. Other types of diaphragmatic hernias present different problems and will not be considered.

A diaphragmatic hernia is found frequently during routine gastrointestinal x-ray examinations, occurring in between 1 to 2 per cent of these studies.[1] Of these, more than 98 per cent are of the hiatal variety.

There are several classifications of hiatus hernia, but that most commonly used divides these defects into four anatomic types. These four types are:

1. The congenital short esophagus with thoracic stomach, a rare condition.
2. The hiatal esophageal hernia with a shortened esophagus.
3. The esophageal hiatal hernia of the sliding variety. This is the most common type.[2]
4. Para-esophageal hernia through the esophageal hiatus.

In the latter two types, the esophagus is of normal length. In type 4, the esophagus remains fixed in the hiatus, the stomach herniating through the opening beside the esophagus. In this variety, the esophago-gastric junction remains below the diaphragm. In type 3, the lower end of the esophagus is not fixed, but withdrawn into the posterior mediastinum with a portion of the stomach. Here, the esophago-gastric junction is drawn up above the diaphragm. For practical purposes, types 3 and 4 will be considered together, since their differentiation is only of academic interest. In type 2, shortening of the esophagus is apparently due to scar contracture, a result of ulceration and esophagitis.

Since an accurate anatomic knowledge of the parts concerned is necessary in any hernia repair, brief mention should be made here of the normal hiatal structure and the basic faults found in hiatal defects. Carey and Hollinshead[2] have shown that the normal diaphragm about the hiatus is formed from the right crus which splits into a deep and superficial layer. In a few cases, a few fibers from the left crus cross to the right over the aorta to form part of the right margin of the hiatus. This, however, is uncommon. The transversalis fascia of the abdominal wall is continued on to the inferior surface of the diaphragm as the diaphragmatic fascia. As it approaches the esophagus, it is called the diaphragmatico-esophageal fascia or the phreno-esophageal ligament. This ligament passes through the hiatus to insert in the lower part of the esophagus 2 or 3 cm. above the esophago-gastric junction. Enough strength and flexibility are present in this structure to resist traction of the stomach into the thorax and yet allow some movement of the cardia with swallowing and change of body position.

Carey and Hollinshead have pointed out that there are three basic defects present in hiatal hernia: (1) The first is a redundant peritoneal sac which extends through the hiatus and is located on the anterolateral aspect of the upper part of the stomach and the lower part of the esophagus. This sac does not pass all the way around the underlying organs. (2) The second basic defect is stretching of the phreno-esophageal ligament. (3) The third defect in hiatal hernia is distortion or weakness of the right crus, the muscular collar of the hiatus.

Symptoms and Complications

In hiatus hernia, symptoms may be mild and not particularly related to the size of the defect. Small sliding hernias may produce great distress. Often the manifestations are vague, but the disease should be suspected in patients with abdominal symptoms or persistent refractory anemia. Certainly, it is reasonable to think that a large number of so-called pseudo-cardiacs and air-swallowers actually are suffering from undiscovered hiatal hernias. In our own experience, the dis-

---

From the Department of General and Thoracic Surgery, The Duluth Clinic, Duluth, Minnesota.

ease has in several instances been mistaken for coronary heart disease.

A hiatus hernia syndrome has been described[3] consisting of: (1) a feeling of pain, fullness or distress in the epigastrium or substernal area, coming on at the beginning of a meal. It may be so severe that the patient has to stop eating. (2) When the patient gets up and walks about, symptoms suddenly disappear, and the patient can continue the meal. It has been said that this symptom complex practically permits a diagnosis of hiatus hernia.

Frequent symptoms are pain, distress, eructation, vomiting, dyspnea, palpitation, belching, and weakness. Substernal burning is not uncommon and may be due to esophagitis. We have seen several patients who have complained of burning pain in the neck, jaws, and ears. Incompetence of the so-called cardiac sphincter permits regurgitation of acid stomach contents resulting in sour eructations or acid regurgitations, and even esophagitis. Some patients note that bending over results in epigastric distress and the feeling of hot, sour fluid running down into the mouth. Because of the position of the esophago-gastric junction above the diaphragm and the loss of the natural sphincter action normally present at the hiatus, this latter symptom seems to be more characteristic of the sliding variety of hiatal hernia. Frequently, we encounter individuals who assert that lying down after a fairly large meal will almost certainly produce trouble, and often there is distress at night that is relieved by getting up and walking around.

Hemorrhage with secondary anemia is said to be quite common although we have seen this complication in only three patients. Peptic ulcer of the esophagus, due to regurgitant esophagitis, may occur and has been seen in one of our patients. Perforation with mediastinitis may result. If severe ulceration of the esophagus continues untreated, stenosis and cicatricial shortening of the esophagus may result. This end result may require dilatation of the structures, and some authors have even resorted to resection and esophagogastrectomy.

The diagnosis may be suspected from the history. It must be finally made by the radiologist. Many technical points have to be considered in the roentgen diagnosis of hiatal hernia, and these will not be considered here. Of importance, however, is the demonstration of length of the esophagus, position of the esophago-gastric junction and its relation to the diaphragm, and size of the hernia. Often, only the head-down position will reveal the defect. Large, irreducible hernias are detected easily, but the small ones are often quite difficult to demonstrate. For this reason, it is often advisable to repeat the x-ray examination in the event of negative findings when the clinical indications are typical. In one of our patients, three x-ray examinations were necessary before the hernia was finally discovered.

Esophagoscopy is of great importance. It is the only way to evaluate adequately the degree of regurgitant esophagitis. Every patient with an esophageal hiatus hernia who has a history of dysphagia or bleeding should be esophagoscoped. Some people feel that all patients with an esophageal hiatus hernia should have such an examination preoperatively. The endoscopist can provide the surgeon with valuable information, including a fairly accurate estimate of length of esophagus, a very important factor not always apparent in the x-ray examination. Lastly, esophagoscopy will rule out any unsuspected lesion such as carcinoma low in the esophagus or in the cardia, mucosal cyst or tumors, or diverticulum of the esophagus.

Patients with small hernias and minimal symptoms may be handled satisfactorily by medical management. This includes anti-acids, antispasmodics, and more frequent smaller bland feedings. We feel it is also important to elevate the head of the bed on one-foot blocks. For the obese patient, a reduction plan is most important.

In all cases, except in those patients with very large hernias or those with severe symptoms or regurgitant esophagitis, we try a period of conservative remedy. Many internists, who usually see these people first, seem to feel that such hernias, especially small ones, seldom produce symptoms and do not deserve surgical treatment. Nevertheless, those we see who come to operation have usually been on a plan of medical therapy without much success. It is the opinion of some surgeons that symptoms are really complications, and since all hernias should be repaired before complications develop, so should hernias of the esophageal hiatus. We have not assumed quite as radical a position, feeling that each individual, his symptoms and circumstances, requires particular consideration. Certainly, not every patient with hiatus hernia needs an operation.

If gastrointestinal symptoms are not sufficiently relieved by a conservative plan or if complications do arise, surgical correction is advisable and, at times, mandatory. Contraindications to operative relief are: (1) undue esophageal shortening, (2) obesity of marked degree, (3) a good chance of later pregnancies, (4) symptoms not certainly due to the hernia, (5) poor general condition of the patient. Absolute contraindications to the procedure are the very short esophagus with or without a stricture and the extremely obese patient who will not diet.[4]

Surgical repair may be by the abdominal or thoracic approach. One is afforded better visualization of the defect, the sac, and the esophagus by the thoracic approach, but, unfortunately, a thorough abdominal exploration is not so easily done. In our experience, a thoracic approach has been entirely satisfactory, and we prefer it in the majority of cases.

Our thoracic procedure has been generally patterned after that described by Allison[5] with a few modifications of our own. The left chest is opened through the bed of the resected eighth or ninth rib. The inferior pulmonary ligament is divided, and the mediastinal pleura incised. A previously inserted nasal tube facilitates identification of the esophagus. The latter structure is mobilized together with the hernial sac and stomach. Some care must be exercised to avoid entering the right pleural space. A traction tape is passed around the esophagus to aid in maintaining reduction of the hernia later. A short incision is made in the left leaf of the diaphragm between the muscular and tendinous portions but avoiding incising the esophageal hiatus. Through this incision, the fingers of the left hand are passed, and then the fingers are thrust upward into the hiatus to identify and tent-up better the peritoneal sac. The latter is opened from above and is partially excised. It must be remembered that the sac does not encircle the viscus completely. Therefore, it cannot be excised as one does a redundant peritoneal sac in the repair of the usual inguinal hernia. The esophagus is then drawn downward by means of the traction tape which is passed through the esophageal hiatus; that is, through the opening in the sac and then back out through the incision in the diaphragm. The superior cut margin of the phreno-esophageal ligament, which, as we mentioned earlier, had been part of the hernial sac, may then be sutured to either the thoracic surface of the diaphragm or the abdominal surface of the diaphragm. We have used both methods and find that the former is easier. A few interrupted silk sutures are used for this. The suturing of the phreno-esophageal ligament should maintain the reduction. Additional sutures may be placed between the cardia and the diaphragm from below as recommended by some authors.

The next and probably most important step is to identify and clean carefully the fibers of the right crus and to suture them behind the esophagus. Usually, two or three interrupted silk sutures suffice. This closure is made snug enough to allow the tip of the fifth finger to be inserted between the esophagus and the sutured crus. If one wants to be especially certain that harmful narrowing will not occur, the most superior suture next to the esophagus may be of chronic catgut. This will allow subsequent dilatations if the new hiatus is too tight. Finally, the incision in the diaphragm is closed with interrupted silk, the mediastinal pleura closed likewise, and the chest wall reconstructed. Three catheters are left in place for suction drainage for twenty-four to forty-eight hours. It should be mentioned that we rarely crush the phrenic nerve.

We have operated upon twenty-four patients for diaphragmatic hernia. Eighteen of these patients had esophageal hiatus hernias. Only one of these was of the para-esophageal type. Eight of these patients were males and ten females, a proportion not in accord with figures generally reported. Most of our patients were of the stocky, sthenic build, and several had been considered psychoneurotic following earlier examinations. One fifty-two-year-old woman complained of postprandial throat pain which was completely relieved by repairing her esophageal hiatus hernia.

Only five patients had esophagoscopy preoperatively, but esophagitis was found in four. One of these patients had a peptic ulcer of the esophagus with a refractory anemia which was cured by repairing his hernia.

A throacic repair was performed in sixteen of the eighteen patients. Medical treatment had been given a thorough trial in all. There were no operative deaths, and the average postoperative hospital stay was only nine days. Complications

Lymphosarcoma

Unusual Extranodal Primary Manifestations

CLEON R. HOLLAND, M.D.
and WALLACE A. MERRITT, M.D.
Rochester, Minnesota

THE initial manifestation of lymphosarcoma, in the majority of cases, is enlargement of superficial lymph nodes. We wish to report four cases in which the primary symptoms arose in extranodal sites. A limited review of the literature indicates the relative rarity of lymphosarcoma in which the primary symptoms arise extranodally.

Lymphosarcoma may arise in any organ which contains lymphoid aggregates. At the New York Memorial Hospital[1] visible and palpable external glandular swelling contributed the first evidences of the disease in 65 per cent of 196 patients with this condition. Symptoms referable to the abdomen occurred in 17.5 per cent of cases. In 11.6 per cent, the first complaint concerned difficulties in the upper part of the respiratory tract. Thoracic symptoms were first to appear in only 3.6 per cent, and pain in bone occurred initially in 1.83 per cent. Systemic manifestations, including fever, sweating and loss of weight, are conspicuously absent until the late generalized stage of lymphosarcoma, in contradistinction to what happens in Hodgkin's disease.

One has only to read some of the older literature on disease of the lymph nodes to recognize the confusion that has existed in the terminology of the various types of lymphomas. For this reason, comparison of statistics concerning lymphosarcoma as it affects various organs, based on reports in the literature, is difficult.

During the past four years we have seen four patients in whom lymphosarcoma was first manifested by symptoms referable to extranodal sites. The organs involved were an extra-ocular muscle, the frontal bone of the head, the left lung and the prostate gland. In three cases, the disease later became generalized.

Report of Cases

Case 1.—A white woman, fifty-seven years old, registered at the Mayo Clinic on January 17, 1949, complaining of a sensation of a foreign body in the left eye of approximately six months' duration. A firm mass was noted on the left eyeball at about the insertion of the inferior rectus muscle. It was known that the patient had had a moderate degree of hypertension for approximately fifteen years. In 1946 she had complained of two attacks of vertigo, and a cerebrovascular accident had been suspected. Blood pressure in 1949 was 210 systolic and 115 diastolic, expressed as millimeters of mercury. Except for moderate obesity, the physical examination disclosed nothing abnormal; adenopathy or splenomegaly was not noted.

On January 18, 1949, the inferior rectus muscle of the left eye was excised. It was found to contain a tumor which on microscopic examination was reported as being a lymphosarcoma of the lymphocytic type. Additional treatment consisted of the application of radium to the region of the left orbit on January 21 and 24, and April 26. After this, the patient noted diplopia when she looked down or to the left.

The patient was next seen on February 19, 1952, complaining of fatigue, apathy, loss of appetite and a nonproductive cough. Physical examination disclosed mild hypertension, obesity and a cervical polyp, which was removed. There was no significant adenopathy or obvious recurrence of the left orbital tumor. A moderate number of erythrocytes were noted on microscopic examination of the urine. There was a mild degree of hypochromic anemia, and the erythrocyte sedimentation rate was 105 mm. in one hour (Westergren). Roentgenologic examination of the thorax showed changes consistent with the findings of multiple pulmonary metastasis (Fig. 1a). Because of the hematuria, excretory urograms were made which showed no evidence of renal neoplasm. Roentgen therapy to the thorax was employed; marked regression in the multiple nodular densities ensued (Fig. 1b).

In June, 1952, a tumor was noted in the right upper eyelid. This was treated with roentgen-ray irradiation in June, July and August, 1952.

A nodule in the right lower eyelid was treated with roentgen rays in November, 1953.

In April, 1954, a nodule in the left lower eyelid was treated with roentgen rays.

Read at the meeting of the Southern Minnesota Medical Association, Albert Lea, Minnesota, September 12, 1955.

Dr. Holland is a Fellow in Surgery, Mayo Foundation, and Dr. Merritt is from the Section of Medicine, Mayo Clinic and Mayo Foundation. The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

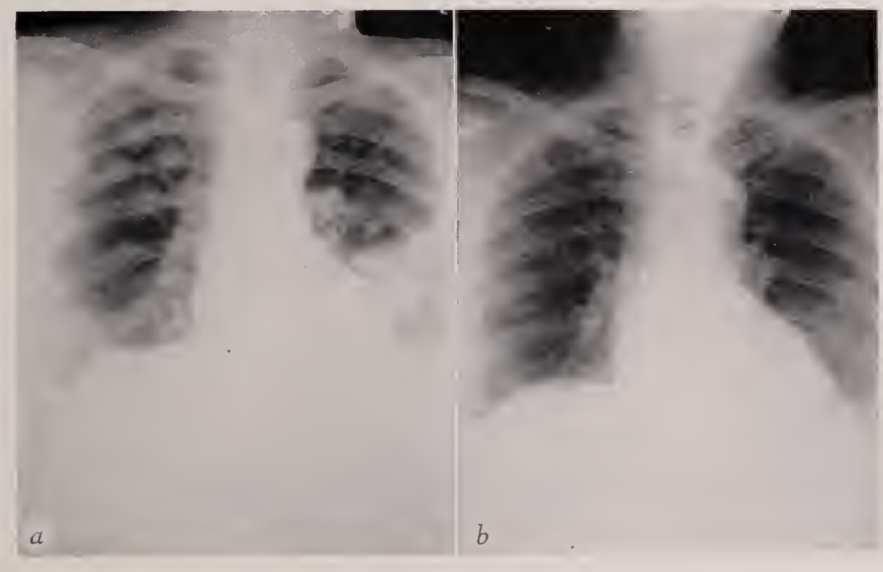

Fig. 1 (Case 1). (a) Thoracic roentgenogram on February 20, 1952, showing changes consistent with the presence of multiple pulmonary metastatic lesions. (b) Thoracic roentgenogram six months later, after roentgen therapy. Note clearing of lesions.

In January, 1955, the patient noted a burning pain in the right posterior thoracic region. At this time roentgenologic examination of the thorax revealed four nodular lesions in the field of the right lung and two similar lesions in the field of the lower part of the left lung. (Fig. 2). Roentgen therapy was again directed over the thorax. It is interesting to note that in spite of specific examination of superficial nodal areas, at no time has there been significant enlargement of lymph nodes.

Comment on Case 1.—In the group of patients seen at New York Memorial Hospital[1] the orbit was involved primarily in 0.5 per cent. Duke-Elder also mentioned lymphosarcoma in enumerating tumors involving the eye, without specifically mentioning the extra-ocular muscles.

Case 2.—A sixty-three-year-old farmer registered at the Mayo Clinic on January 6, 1955. His history was interesting in that he had been treated at the same clinic in 1936 for proved cervicofacial actinomycosis. The illness he had in 1955 had begun two months prior to his admission, when he had noted frontal headaches that were present day and night. Three weeks prior to this admission he had first noted three bony protrusions in the frontal area of the scalp, each approximately 1 cm. in diameter. One and a half years previously he had noted the onset of increased shortness of breath on exertion, and on one occasion he awoke at night feeling short of breath. There was no history of angina or edema of the ankles.

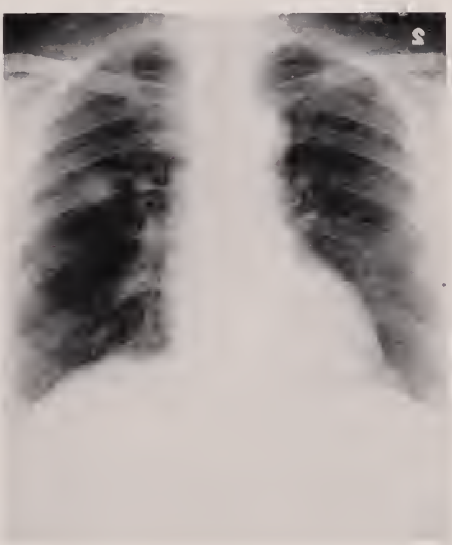

Fig. 2 (Case 1). Thoracic roentgenogram on January 21, 1955, showing recurrence of lesions in both lungs.

The bony protrusions in question were readily palpable over the frontal area of the skull. The heart was moderately enlarged, but there was no clinical evidence of increased venous pressure, pulmonary congestion, or edema of the ankle. The blood pressure was 122 systolic and 102 diastolic, in millimeters of mercury. The pulse rate was 124 per minute, and the electrocardiogram revealed delayed A-V conduction and left bundle-branch block. There was no significant lymphadenopathy and the spleen was not enlarged. Albuminuria was graded 3, and erythrocyturia, 2. Values for hemoglobin, erythrocytes and leukocytes were normal. The sedimentation rate was 21 mm. in one hour (Westergren). The value for urea was 64 mg. per 100 cc. of blood, and the reaction of the Kline test was negative.

A roentgenogram of the thorax showed cardiac enlargement; roentgenograms of the skull demonstrated destructive lesions of the frontal bone. Results of neurologic examination were negative. It was decided to obtain specimens of the lesions in the frontal bone for biopsy. After digitalis had been administered to the patient, a specimen of tissue was removed from one of the nodules on the frontal bone by Dr. R. H. Miller, of the Section of Neurologic Surgery. Biopsy demonstrated a picture consistent with the diagnosis of lymphosarcoma.

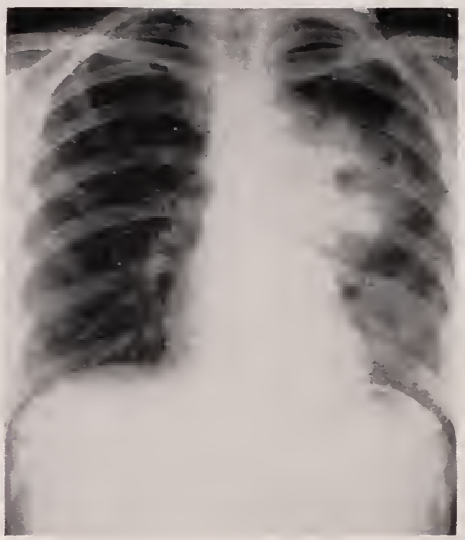

Fig. 3 (Case 3). Thoracic roentgenogram on April 5, 1954, showing extensive consolidation in the upper lobe of the left lung and multiple areas of cavitation.

Roentgen-ray treatment was directed to the frontal region of the skull daily for ten days, after which the nodules disappeared and the headaches were relieved.

Two months later the headaches returned, with associated swelling of the left supra-orbital ridge. Because of the atypical nature of the bony involvement, sternal aspiration was performed and hypocellular marrow was obtained thereby. Malignant cells were not found, nor were multiple myelomas. A second course of roentgen-ray therapy consisting of ten treatments to the left frontal region was administered.

Within one week bony enlargement of the right supra-orbital ridge was noted, and it rapidly increased.

Within three weeks of the time of the last treatment massive bony enlargement of the right frontal region was evident, while the left side remained normal. The right eye was swollen shut. A third course of roentgen-ray therapy consisting of eight treatments was directed to the whole frontal area, including the orbital areas. After this, the swelling subsided and the pain disappeared.

Comment on Case 2.—Cortical or medullary involvement of bone is relatively common in the terminal stages of lymphosarcoma. However, involvement of bone as a primary manifestation of the disease is relatively rare. The New York Memorial Hospital workers reported it as occurring in only 1 per cent of their cases. In the presence of lymphosarcoma the lesions are mostly osteolytic (85 per cent). Localized pain and tenderness are the most frequent clinical indications of lesions of bone in this disease.[2]

Case 3.—A thirty-nine-year-old white woman registered at the Mayo Clinic on April 5, 1954. She said that in January, 1953, an infection of the upper part of the respiratory tract had been followed by generalized pruritus and recurrent infections of the skin. Increased nervousness and fatigue gradually developed, and a cough started which was productive of purulent sputum, occasionally blood-streaked. Various antibiotic agents were administered, as well as vitamin B_{12} and iron. At no time did the patient experience pain in the chest or dyspnea.

At the time of her admission she had lost approximately 8 pounds. The physical examination disclosed nothing abnormal. Roentgen-ray examination of the thorax showed changes considered to be those of extensive consolidation in the upper lobe of the left lung and multiple areas of cavitation (Fig. 3). There was a small patch of pneumonitis with central cavitation in the lingula. The value for hemoglobin was 10.6 gm. per 100 cc. of blood; erythrocytes numbered 4,010,000 and leukocytes 7,600 per cubic millimeter of blood. The erythrocyte sedimentation rate was 109 mm. in one hour (Westergren). The reaction to tuberculin skin tests was negative in first and second strengths. Microscopic examination of the sputum did not reveal evidence of tuberculosis or malignant cells. Subsequent culture of specimens of sputum gave negative results for tubercle bacilli as well as for fungi. Bronchoscopic examination showed purulent secretions exuding from the bronchus of the upper lobe of the left lung, but no evidence of obstruction.

The patient entered the hospital for a ten-day period of treatment with nebulized penicillin and streptomycin, as well as the parenteral administration of the same drugs. Roentgenograms of the thorax at the end of this period disclosed no appreciable changes in the appearance of the lesions in the lung.

On April 21, 1954, Dr. John W. Kirklin explored the left lung. The upper lobe was found to be massively involved with an inflammatory and cavitary lesion. There was also a similar but smaller lesion in the posterior, basilar segment of the lower lobe. Left pneumonectomy was performed. The surgical pathologist reported lymphosarcoma (Hodgkin's type) extensively involving the upper lobe and a small nodule of tumor in the lower lobe. In view of the apparent localized nature of the process, no further treatment was given. The patient was discharged from the hospital on the eleventh postoperative day.

The patient returned for re-examination on August 2, 1954. At that time there was no evidence of recurrence of the lymphosarcoma, and a roentgenogram of the thorax showed no changes in the right lung. The pruritus had receded markedly.

In early January, 1955, the patient noted a dull, aching soreness in the left shoulder, extending into the neck and down the left arm to the elbow. The pruritus became more troublesome. The patient said that the consumption of any alcoholic beverages aggravated the pain.

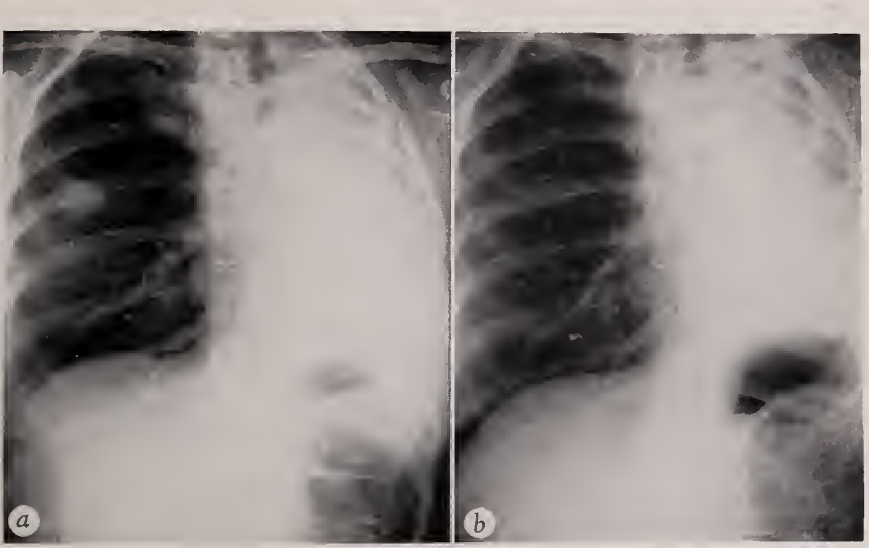

Fig. 4 (Case 3). (a) Thoracic roentgenogram on January 24, 1955, showing the results of left pneumonectomy and two nodular areas in the right lung. (b) Thoracic roentgenogram two months later, showing disappearance of nodules in right lung after roentgen therapy.

She was seen again on January 21, 1955, and at this time the physical examination showed no significant abnormalities. A roentgenogram of the thorax showed the results of left pneumonectomy and two nodular areas in the right lung near the anterior ends of the first and third ribs (Fig. 4a). The latter were assumed to be caused by lymphosarcoma. Roentgen-ray therapy was administered to the thorax.

After this, the patient felt much improved until March 14, 1955, when she noted increased weakness, cough, low-grade fever and more intense pruritus.

She was again examined on March 28, and except for excoriations over the skin, nothing abnormal was found. Roentgenograms of the thorax showed that two nodular lesions in the right lung had disappeared (Fig. 4b). While there were no demonstrable focal areas of lymphosarcoma, it was felt advisable to administer nitrogen mustard. The patient received this form of treatment in her home city.

Comment on Case 3.—Primary lymphosarcoma of the lung has been reported infrequently in the literature; however, secondary involvement is not uncommon. The diagnosis when the process is primary in the lung is made only at the time of operation, and microscopic examination of removed tissue is then necessary.[3-5]

Case 4.—A thirty-two-year-old white farmer from Nebraska registered at the Mayo Clinic on June 28, 1951. He was admitted to a hospital the same day. His history was not significant, except that he had undergone hemorrhoidectomy elsewhere in March, 1951. Three months prior to his admission he had noted the onset of frequent urination, day and night. These symptoms increased in severity, and a week prior to his admission he noted general malaise and felt an orange-size mass in the suprapubic region. He received a urinary antiseptic agent, and at the time of his admission the frequency of urination had diminished and the suprapubic mass had disappeared.

We found that the blood pressure was 140 systolic and 80 diastolic, in millimeters of mercury. There was evidence of some dehydration. Rectal examination revealed an ill-defined mass in the region of the prostate gland; this mass spread laterally and seemed to surround the apex of the bladder. There was no significant enlargement of lymph nodes and the spleen was not palpable. Excretory urography disclosed a moderate degree of hydronephrosis involving both kidneys (Fig. 5a). Albuminuria was graded 3, pyuria, 1 (on the basis that the least amount is grade 1 and the greatest amount, 4) and erythrocyturia, 1 (on the basis that the greatest amount is graded 5). Values for hemoglobin and the erythrocyte count of the blood were normal. The sedimentation rate was 101 mm. in one hour (Westergren). The value for urea was 42 mg. per 100 cc. of blood. Roentgenologic examination of the thorax, pelvis and spinal column disclosed nothing abnormal.

Cystoscopic examination performed by Dr. E. N. Cook disclosed chronic, diffuse cystitis, with considerable shagginess and mucosal hypertrophy over the trigone and base of the bladder. Biopsy of a section of tissue from the region of the prostate gland demonstrated lymphosarcoma of the lymphocytic type.

Roentgen-ray treatment over a fifteen-day period was directed to the bladder and perineum. The patient returned home on July 23, 1951.

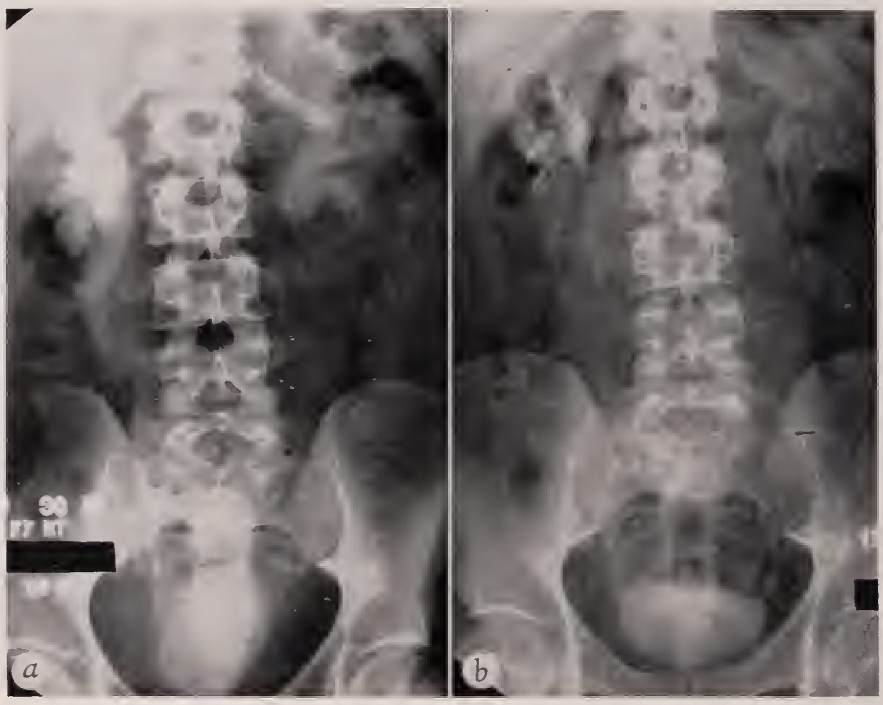

Fig. 5 (Case 4). (a) Excretory urogram on June 30, 1951, showing moderate degree of hydronephrosis involving both kidneys. (b) Excretory urogram four months later, showing essentially normal-appearing renal pelves.

The patient returned for re-examination on October 31, 1951. At that time he had no complaints. The prostate gland seemed to be normal at rectal examination. Excretory urography revealed essentially normal-appearing kidneys (Fig. 5b). Cystoscopic examination demonstrated a minimal amount of prostatic fullness. No treatment was given.

Results of examination again were normal on February 1, 1952, but when the patient returned on June 6, 1952, an enlarged lymph node was found in the left posterior cervical triangle. There was also a mass in the midabdomen, considered probably to represent periaortic lymphadenopathy, and there was some degree of infiltration of the prostate gland. Roentgen-ray therapy was directed to these three areas.

In September, 1952, the patient noted a mass just above the navel, and he received roentgen-ray treatment to this area.

In December, 1952, perirectal infiltration associated with diarrhea was found, and again he received roentgen-ray treatment. In February, 1953, additional involvement of the rectum was discovered, with partial obstruction of the bowel. Because of the unfavorable response to roentgen-ray treatment, a course of nitrogen mustard was administered intravenously. The patient died at home in the spring of 1953.

Comment on Case 4.—In 1949 Waller and Shullenberger[6] reviewed twenty-one cases of primary lymphosarcoma of the prostate gland reported in the literature, and added one new case. The age of the patients reported ranged from twenty-two to sixty-eight years, and the average age was forty-one years. The authors wrote that lymphosarcoma of the prostate gland should be considered when a large tumor of that structure occurs which is not hard or nodular, and when the patient is middle-aged. Sarcoma of the prostate gland, on the other hand, is a disease of children.

Comment and Summary

Four cases of lymphosarcoma have been reported in which the initial manifestations presented themselves in extranodal sites. The occurrence of the process in such sites probably is more frequent than is true of Hodgkin's disease. The organs or structures primarily involved were: (1) an extra-ocular muscle, (2) the frontal bone of the head, (3) the left lung, and (4) the prostate gland. Difficulty in diagnosis arises when there is neither superficial lymphadenopathy nor definite evidence of enlargement of more deeply seated

Treatment of Severe Injuries of the Hand

LESTER W. CARLANDER, M.D.
Minneapolis, Minnesota

THE great importance of the functional capacity of the hand to the skilled craftsman, the artist or musician, the physician and surgeon, is of course apparent to everyone. We must, however, not overlook the fact that a serious injury to the hand with resultant crippling may be equally disastrous to the laborer, the farmer, the housewife; indeed a handicap to anyone. The miraculous capacity of the human hand was the text of an article in a recent lay magazine entitled "Your Hands are Incredible." In this article, John Pfeiffer points out the following facts about the dexterity of our hands:

1. The pianist, Paderewski, playing at top speed, struck 120 notes a second, varying the rhythm and striking force with amazing control.
2. It is estimated that the five fingers in combination can assume any one of 300 million possible useful positions.
3. About one-third of the 5 million tiny cutaneous sense organs of the entire body are located in the hands.
4. During World War II, blind workers using touch alone actually did a surprisingly superior job of sorting precise machine parts for radar equipment than sighted workers using micrometer gauges.
5. It is, of course, the capacity for the human thumb to rotate into position of opposition that separates the homo sapiens from the higher apes.

The human hand has been described as an organ of grasp, an organ of sensation, and an organ of expression. All injuries of the hand, from the time they are first seen, should be treated with the purpose in mind of restoring this high degree of functional capacity. With this emphasis on early restoration of function, there are a few general principles that are worthy of mention.

General Considerations

1. Early closure and coverage of wounds. The scarring and fibrosis that accompanies delayed healing and open wounds results in stiffness and loss of function in the hand.
2. Treat swelling from the first. This is particularly true in crushing types of injury where swelling may be severe. Prolonged swelling restricts interphalangeal motion and is accompanied by fibrotic changes in the capsules of the metacarpal-phalangeal and interphalangeal articulations. Treatment of swelling may include constant elevation, compressive type dressings, and stellate ganglion blocks.
3. Immobilize only the portion of the hand that is necessary and this should be immobilized in functional position (partial flexion of the metacarpal-phalangeal and interphalangeal joints).
4. Early mobilization of the hand. Active and passive motion should be started as soon as consistent with the healing of the injuries, often before complete bony healing is accomplished.
5. The main responsibility of the doctor first treating an injured hand is proper treatment of the wound. The importance of obtaining uninfected and rapid healing cannot be over-emphasized and should be the main objective of the emergency treatment.

Major injuries to the hand, as occasionally seen from punch presses and frequently seen with corn picker injuries on the farm, may involve loss of some of the component parts of the hands. Viable and possibly viable tissue in general should be preserved. This is particularly true with regard to the thumb and with sole remaining portions of fingers opposed to the thumb. It is important in dressing these injuries to maintain the thumb and first metacarpal in position of opposition so as to avoid contraction of the web and inability to oppose the thumb to the remaining hand. Care may include early skin grafting in order to prevent undue sacrifice of remaining skeletal parts. Rehabilitation may include use of prosthetic appliances or occasionally transposition of finger to replace the thumb.

Severe injuries to the hand may often combine damages to the skeletal and soft parts. Judicious use of primary amputation may be indicated where

---

Read at the annual meeting of the Minnesota State Medical Association, Minneapolis, May 25, 1955.

damage to the metacarpal-phalangeal or proximal interphalangeal joints makes return of function impossible, or where the traumatic amputation leaves an ineffective stump. This should be done only when some of the remaining digits are intact and at times may be preferable to long periods of disability and consequent economic loss.

In cases where there is combination of fractures in phalanges and metacarpals associated with tendon injuries, it is often best to obtain stabilization and healing of the bony components and passively mobile joints before attempting repair of the tendon injury. Repairing all components primarily may leave too long a period after repair before rehabilitation can be started, resulting in binding down of the tendons and diffuse stiffness of the hand. The use of fine Kirschner wires to immobilize fractures may allow resumption of motion before complete bony healing of the fracture is accomplished.

Tendon and Nerve Injuries

The difference in the results in repair of extensors tendons from that of repair of flexor tendons has long been apparent to all. Extensor tendons for the most part are single tendons and do not slide in sheaths. Their motion back and forth is possible because of the long fiber type of areolar tissue about them. Repair usually consists simply of approximation by suture, and splinting of the wrist and fingers so as to relax all tension on the anastomosis. Repair of flexor tendons on the other hand, is not only technically more difficult but also prone to give much poorer results. This is particularly true in the region of the hand extending from the distal palmar crease to the proximal interphalangeal joint. In this area primary repair of flexor tendons has an extremely poor prognosis. For this reason, Dr. Sterling Bunnell has labelled this area "no man's land." In a recent review of some 500 tendon injuries in the hand, Dr. M. F. Hauge[1] presented some interesting facts. The seriousness of flexor tendon injuries in "no man's land" is attested to by the results of ninety-eight primary tendon sutures in this area, in which Dr. Hauge also included the thumb. There was one successful suture (in the thumb) and three fairly satisfactory results (two in the thumb) and ninety-four failures. When we look to see what is unique about this area of the hand anatomically, we find, of course, that in this region both the flexor sublimis and flexor profundus tendons run together through a very tight reinforced portion of the tendon sheaths. Tendons injured and repaired in this area tend to bind down during the process of healing, subsequently do not slide normally, and finally flexion is accomplished, usually limited to the metacarpal-phalangeal articulation. For this reason, it is becoming more and more generally believed that lacerations of the flexor tendons in this portion of the hand are best treated primarily by simple cleaning of the wound, closure of the wound, obtaining flexible joints by early passive motion, and then subsequent removal of the flexor sublimis tendon and replacing the flexor profundus tendon by free tendon graft.

A second serious special injury presenting difficulty of technical repair is the injury of the median nerve at the base of the thenar eminence. As the median nerve emerges in this area, it branches into sensory branches to one-half the ring finger, to the middle finger, the index finger, and the thumb, and sweeps back into the thenar eminence with motor branches to the opponens, short abductor and one head of the short flexor muscles. The anatomy is intricate when intact and, when altered by trauma, can be difficult for any of us.

As we have mentioned in the presence of extensive soft tissue and skeletal injuries it may be better to close these wounds, to get good healing and pliable joints, and to plan on secondarily accomplishing tendon or nerve repairs or grafts, rather than to attempt multiple primary tendon and nerve repairs.

Dr. Joseph H. Boyes, past president of the American Society of Hand Surgery, has stated that there are three components to the trade of any skilled craftsman: materials, principles, and techniques.

As craftsmen in the repair of the injured hands, the "material" with which one works is the anatomy of the hand: the bones, the joints, the muscles and tendons and their sheaths, the nerves and the blood vessels, and the skin. These are the lumber, the metals, and the paints with which we must be familiar to accomplish good work.

The principles involved in hand surgery are represented by the knowledge and judgment of what should be done with each of the various types of injuries which we see in order to assure return of function.

It is our technique in dealing with this material and applying these principles that to a great extent

(Continued on Page 164)

The Use of Liquid Oxygen in Dermatology

CARL W. LAYMON, M.D., and
CHARLES J. BALOGH, M.D.
Minneapolis, Minnesota

LIQUID oxygen was used for the treatment of cutaneous diseases in Minneapolis by Irvine and Turnacliff,[1] who reported their findings in 1929. For the next two decades little attention was paid to this modality in the Upper Midwest. We became interested in the use of liquid oxygen several years ago following discussions with Dr. Ashton L. Welsh of Cincinnati. Kile and Welsh (1948) reported their results in the treatment of more than 1,000 patients with disorders of the skin. They observed that liquid oxygen was an effective local destructive agent in patients having warts, hemangiomas, keratoses, or leukoplakia.

A. C. White (1899)[2] reported originally on the use of liquid oxygen by dermatologists. Following Pusey's[3] paper concerning the dermatologic uses of solid carbon dioxide, liquid oxygen went into eclipse. It was due largely to the reports of Kile and Welsh (1948)[4] and Allington (1950)[5] that interest in the use of liquid gases as cryotherapeutic agents in dermatology has been stimulated. In a paper (in press) presented recently (April, 1955) before the American Dermatological Association, Dr. A. Fletcher Hall, of Santa Monica, California, voiced his enthusiasm concerning the use of gaseous refrigerating agents in the treatment of selected cutaneous disorders.

Allington stated that in recent years the commercial demand for oxygen and nitrogen has led to the production of these elements in almost pure form and in large quantities. The process of manufacture includes the compression and the refrigeration of atmospheric air and then its fractional distillation and chemical rectification. Liquid oxygen boils at —297° F. (—183° C.) at atmospheric pressure. The sublimation point of carbon dioxide is —110.3° F. (—78.5° C.) For a time, liquid oxygen was more easily obtained than liquid nitrogen. When the latter became more commonly available, some workers preferred it because it had the advantage of being largely inert and presented less of a fire hazard than liquid oxygen. Since liquid oxygen is combustible, contact with fire should be avoided, but it is entirely safe to use if reasonable care is taken. Liquid nitrogen is 13° C. colder than liquid oxygen, hence evaporation is more rapid. Because liquid oxygen is delivered to our office daily from Monday through Friday, this is of little practical importance. The material can be transported from the manufacturer in an ordinary thermos bottle carried in a cardboard carton. The use of a Stanley all-steel vacuum bottle obviates breakage and the use of the cardboard container. Kile and Welsh stated that they obtained one liter of liquid oxygen weekly. In our experience this quantity of liquid oxygen evaporates within twenty-four to thirty-six hours, especially during the warm months of summer. For this reason we decided on a daily delivery so that the oxygen would be available when occasion demanded.

Liquid oxygen is applied by means of an ordinary cotton swab or cotton wrapped around a wooden applicator. The latter is dipped into the liquid and applied to the lesion to be treated. The amount of pressure varies according to the depth of the growth, but only slight to moderate pressure is required in most instances since freezing is almost instantaneous. Lesions such as verrucae on the palmar or plantar surfaces require several seconds to become frozen to their complete depth. The area which is being treated turns white rapidly because of the extreme coldness of the liquid oxygen. Pain varies according to the size and depth of the lesion. Shortly after the initial application of the fluid, after the area is blanched, there is little discomfort. As thawing occurs there is an increase in pain which may last for several hours. Mild analgesics are helpful. After lesions have been treated with liquid oxygen, redness and swelling develop within a short time. In a few hours a bulla forms, which

---

From the Department of Dermatology, Minneapolis General Hospital, Carl W. Laymon, M.D., director; and the Division of Dermatology, University of Minnesota, H. E. Michelson, M.D., director.

reaches its height within two or three days. Sometimes the lesion is hemorrhagic, and patients should be warned that this is no cause for alarm. It has been our custom to instruct patients to return in one week, at which time the roof of the bulla is removed, and the lesion dressed. Healing takes place within two to four weeks, depending upon the size and thickness of the lesion. The development of scars is rare, but when they occur, they are soft, thin, and inconspicuous. Keloids occur rarely, if ever. Repeated treatments are necessary occasionally. We have used liquid oxygen mainly in the treatment of verrucae of various types. In our opinion it is the best way to treat plantar warts of the mosaic type.

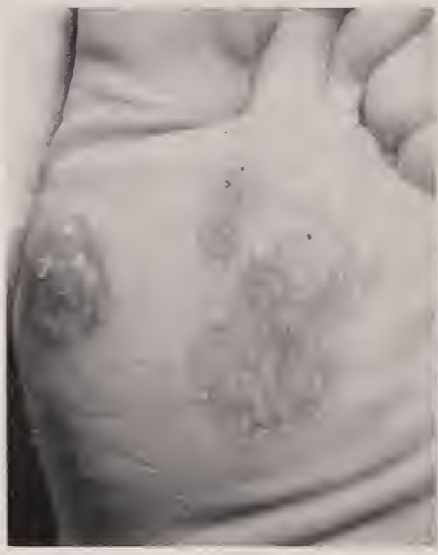

Fig. 1. Bullae one week following the application of liquid oxygen.

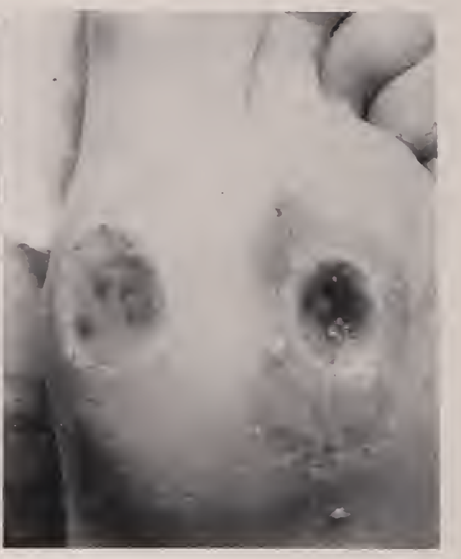

Fig. 2. Appearance of the skin immediately following the trimming of the bullae with small scissors.

Although we have employed liquid oxygen over a period of several years, we have surveyed our statistics only since 1953. Table I is self-explanatory.

In the past two years we have also treated thirty-four cases of hemangioma simplex. In twenty-five the result was considered to be satisfactory. Nine patients failed to return for observation.

It is our impression that liquid oxygen is of definite value in the topical treatment of chronic discoid lupus erythematosus.

We have used this agent in sixteen cases of keloid. In ten an excellent result was obtained, in two satisfactory improvement, in one no improvement, and three patients failed to return for observation.

We have not attempted to use liquid gases in the treatment of leukoplakia which was satisfactorily treated by Kile and Welsh with liquid oxygen and by Allington with liquid nitrogen. Furthermore, we have had no experience in the treatment of dermatitis venenata such as can be produced by various plants.

TABLE I. VERRUCAE TREATED BY MEANS OF LIQUID OXYGEN

	Satisfactory Results	Failures	Failed to Return	Total Cases
Verruca Vulgaris	92	8	39	139
	66%	6%	28%	
Verruca Plana	5	2	3	10
	50%	20%	30%	
Verruca Plantaris	84	11	30	125
(including mosaic type)	67%	9%	24%	
Total	181	21	72	274
	65%	8%	27%	

As aforementioned, our study has been devoted chiefly to verrucae. The latter are extremely capricious in their course, and the results of any treatment are almost unpredictable. Destructive measures such as electrocauterization and electrodesiccation are curative in many cases and x-rays are valuable in others. We believe that liquid oxygen is an excellent addition to our armamentarium for the treatment of warts and

(Continued on Page 158)

Problems in the Clinical Diagnosis and Classification of Ventricular Hypertrophy in Adults

III. Familial Cardiopathy

BEN SOMMERS, M.D.
Saint Paul, Minnesota

THE THIRD and final paper in this series of three presentations concerned with problems in ventricular hypertrophy deals with three cases, all in one family, of the entity termed “familial cardiomegaly” by Evans.[1]

Report of Cases

Case 1.—A twenty-three-year-old white woman was hospitalized in May, 1930, because of shortness of breath on exertion. One week prior to admission, she had attended a picnic, following which abdominal pain, nausea, vomiting, and slight fever had developed. Three days before admission, rather marked fatigability and dyspnea on exertion began.

The blood pressure was 86/70. The skin and mucous membranes appeared paler than normal but cyanosis was not present. A gallop rhythm was described, with a pulse rate of 110 beats per minute. A low-grade fever lasted for one week.

The hemoglobin was 76 per cent (Sahli). Erythrocytes numbered 4,340,000 and the leukocyte count varied from 10,150 on admission to 15,750 on the fourth day of hospitalization. The differential count was not remarkable.

Electrocardiograms showed sinus tachycardia (rate 105-90), slight slurring of the QRS complexes and changes in the T waves. On May 12, the T waves in leads II and III were negative and those in lead I were flattened. The PR interval was 0.18 second. Ten days after the first tracing, the T waves in all three standard leads were reported to be negative. (These data were available on microfilm but the electrocardiograms themselves had not been photographed). The PR interval was 0.20 second, with a heart rate of 102. The patient was dismissed in June as improved, but she was admitted again in July, 1930, because of abdominal pain, bloating and vomiting. She was dyspneic on examination, and the pulse was weak and fast (125). On July 18, cyanosis, hemoptysis and increasing dyspnea required digitalization and use of an oxygen tent. Death occurred on that date.

Necropsy was done by Dr. Kano Ikeda. The heart weighed 400 gm. Moderate hypertrophy of both right and left ventricles was present, with great dilatation of all the chambers. The valves were normal. The circumferences of the valves were as follows: tricuspid, 14 cm.; mitral, 11 cm.; pulmonary, 7 cm.; aortic, 5 cm. The right auricular appendage contained a small mural thrombus and a larger one was present in the left ventricle. The mural endocardium was smooth, except for a small area of grayish thickening in the left ventricle. The coronary arteries were normal. The aortic arch was reduced in diameter, as were the great vessels arising from it.

Microscopic sections of the myocardium were normal, except for swelling and edema in a few areas. The mural endocardium showed slight fibrous thickening; one area in one section showed subendocardial infiltration of monocytes and lymphocytes.

The anatomic diagnoses included cardiac hypertrophy and dilatation, hypoplasia of the aorta and arterial trunks, thrombus of the right auricle and left ventricle, infarct of the right lung with embolism of the pulmonary artery, chronic passive congestion of the organs, pleural effusion, pericardial effusion, and ascites.

Case 2.—A 26-year-old physician, a younger brother of the patient just described, was hospitalized in February, 1936, and died in the hospital on April 8, 1936. Two weeks before admission, he had a severe cold, with a nocturnal cough. Dyspnea began gradually. On the night before admission severe substernal pain began, accompanied by blood-streaked sputum.

His past health had been excellent, except for three episodes of pneumonia in 1915, 1916 and 1920.

Temperature was 100.4°F., pulse rate was 136, and blood pressure was 90/70. Pallor was noted. There was some injection of the pharynx. Many moist râles were elicited at both lung bases, and there was evidence of fluid at the right base. The pulse was described as rapid, weak and of poor volume. The heart was generally enlarged to the right and left. The sounds were all of poor quality, and a pulse deficit of 30 beats per minute was noted. A short presystolic murmur at the apex was present, with some accentuation of the second sound at the apex; the pulmonic second sound was accentuated. The liver was slightly enlarged, but the spleen was not palpable. No edema of the extremities was present on admission.

The patient was placed on the usual “cardiac routine” and remained in bed for three weeks with some improvement. He was then allowed up but it was seen

---

From the Charles T. Miller Hospital, Saint Paul, and the University of Minnesota, Minneapolis, Minnesota.

Part III of this is submitted for admission to the Minnesota Academy of Medicine, April, 1954.

at once that there was a return of orthopnea and dyspnea, and he was put back to bed. Digitalis appeared to help but little. His pulse rate was continually fast, and a gradual increase in the size of the liver was noted. On March 30, he suddenly became worse, with increase in dyspnea and orthopnea, elevation of temperature, and beginning edema of the sacral region. He was placed in an oxygen tent but grew worse and died suddenly two months after onset of symptoms. Laboratory studies were noncontributory.

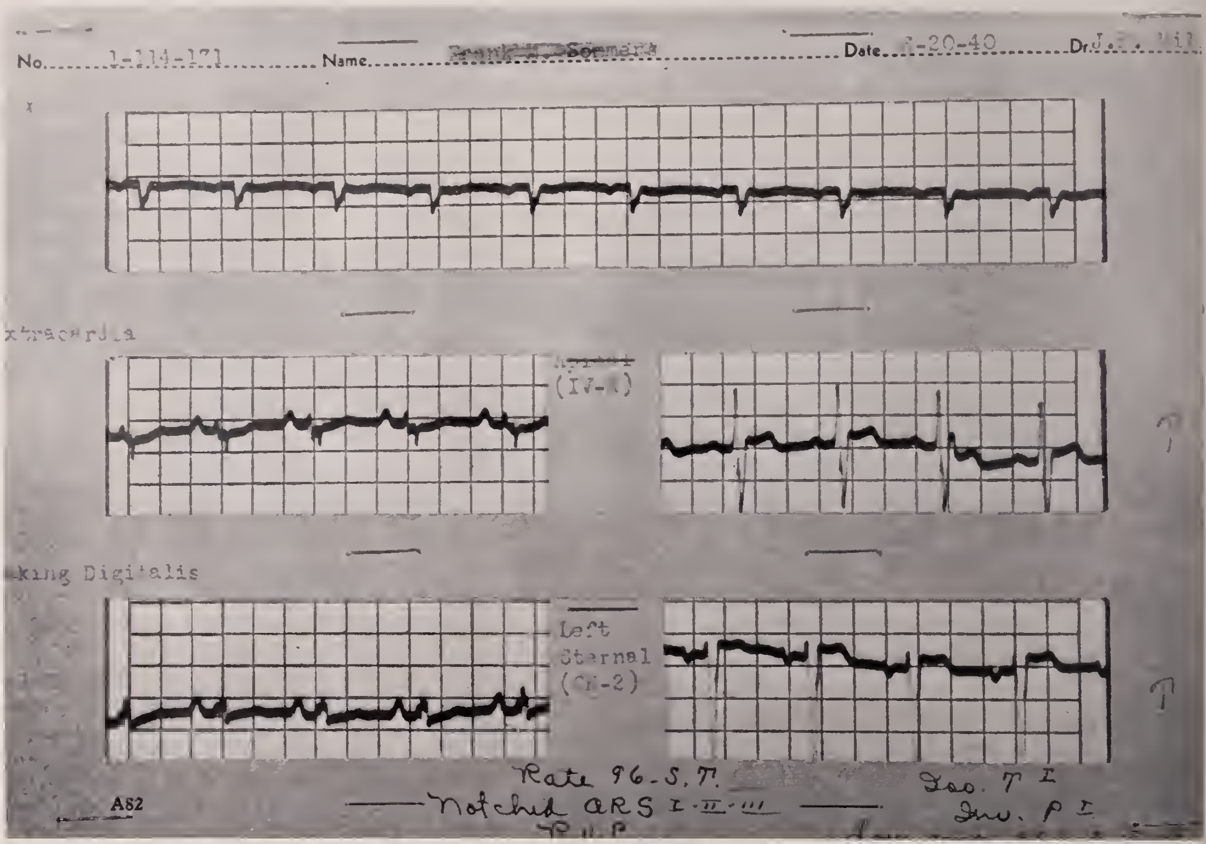

Fig. 1 (Case 3). Electrocardiogram in a twenty-five-year-old man with familial cardiopathy and situs inversus.

Necropsy was done by Drs. Wilson and Blackman. The heart weighed 520 gm. The form was rounded due to apparent increase in size of both the right and left ventricle. The epicardium was normal. All the valves were delicate in appearance and competent. The myocardium was everywhere free of scarring except for a small area beneath a large thrombus of the endocardium of the left ventricle. The coronary arteries were normal.

Microscopic sections were made from every possible portion of the heart and all of them showed essentially the same picture. There was widespread scarring throughout the myocardium without any particular distribution of the scars in relation to arteries. They ranged in size from minute scars involving small portions of muscle bundles to large scars involving several muscle bundles. The muscle fibers in such regions were replaced by pale, pink-staining, rather homogeneous fibrous tissue without inflammatory cells. In other places, a definite chronic inflammatory process was present. In numerous locations beneath the endocardium and in some zones deeper in the wall of the left ventricle, there were groups of lymphocytes and polymorphonuclear leukocytes arranged in thin layers and strands. Some of these had a perivascular distribution.

The anatomic diagnoses included diffuse progressive scarring of the myocardium (idiopathic progressive myocarditis), cardiac hypertrophy and dilatation, mural thrombi in right and left ventricles, chronic passive congestion of organs, infarcts in lungs, spleen and kidney, jaundice, anasarca and diphtheritic esophagitis.

Case 3.—A twenty-five-year-old man, a younger brother of the two patients just described, died of cardiac failure in August, 1940. This patient was hospitalized before death on two occasions, once in March and again in August, 1940. Shortness of breath began one week prior to the first admission and two weeks after onset of a cold with sore throat. Except for a chronic sinus infection, his past health always had been good. He had known since physical examinations for entrance to college that he had complete situs inversus.

The pharynx was reddened and the nasal mucous membrane was injected. Numerous moist râles were elicited over the bases of both lungs posteriorly. The heart was regular in rate and rhythm, and there were no murmurs. The apex beat was on the right side. The blood pressure was 96/74. The liver border was palpable a half finger below the costal margin. Edema of the extremities was absent.

Results of laboratory studies were normal except for a leukocyte count of 17,000, gradually decreasing to 10,880.

A 6-foot film of the thorax showed a slightly enlarged heart, with a cardiothoracic ratio of 49.6 per cent, and complete situs inversus.

Gradual improvement occurred and the patient was sent home on a very restricted regimen. In July, 1940, he was taken to the Mayo Clinic, where Dr. Frederick A. Willius examined him. The electrocardiogram obtained there was loaned for reproduction (Fig. 1). No definite diagnosis was possible, except for dextrocardia and complete situs inversus. Dr. Max Hoffman, physician in charge of this patient, believed that the electrocardiographic changes and the clinical course were suggestive of myocarditis, similar to the condition in the older brother (Case 2).

The second admission to the hospital was necessitated by a great increase in nocturnal dyspnea. Definite cyanosis was seen on admission. Numerous moist rales were again heard, and slight edema was now present.

Results of laboratory studies were much the same, with moderate leukocytosis. The electrocardiogram was reported as showing a 3:1 auricular flutter.

Marked cyanosis and dyspnea required venesection and oxygen, and the patient seemed in imminent danger of death. Gradual improvement occurred, but sudden death took place three days after dismissal from the hospital.

Necropsy was done by Dr. Kano Ikeda. The heart with the pericardium open measured 17 cm. in transverse diameter. It occupied the right side of the thoracic cavity, its apex pointing to the right. There was complete transposition of the heart and great vessels. The heart, together with the ascending portion of the arch, weighed 560 gm. The epicardium was smooth. The myocardium was unremarkable in color or consistency. The left ventricle was 2 cm. in thickness and the right ventricle was 9 mm. A large thrombus was attached to the mural lining of the right and left ventricles near the apices, and one was present in the right auricular appendix. All the chambers were greatly dilated. The mitral orifice measured 12 cm. in circumference, the tricuspid, 14 cm., the pulmonary, 6 cm. and the aortic ring, 5 cm. The aortic arch was greatly reduced in size and considerably shortened. The coronary arteries were normal.

Microscopic sections of the myocardium were entirely normal, except for two fields. One of these showed only a few lymphocytes. The second small field showed a rather severe acute myocarditis involving both the interstitial tissue and also the muscle fibers. Dr. Otto Saphir kindly reviewed these sections and stated that if no other disease were found at necropsy that could possibly account for the myocarditis as a complication, he would believe that this was an instance of isolated myocarditis.

The anatomic diagnoses included dextrocardia and complete situs inversus, hypoplasia of the aorta, cardiac hypertrophy and dilatation, mural thrombosis of the left ventricle and of the right auricle and ventricle, chronic passive congestion of the organs, embolism of the left lower trunk of the pulmonary artery, infarct of the left kidney, an anomalous artery at the lower pole of the left kidney and an azygos lobe of the left lung.

Comment

An older brother and a sister, fifty and forty years of age, respectively, at the time this is written, are living and well. The mother died suddenly of a cerebrovascular accident at the age of seventy. The father is eighty-four years of age. In December, 1954, he successfully underwent removal of a chondroma of the mediastinum; this arose from a rib and weighed 5 pounds. Family records reveal no other similar cardiac conditions.

These two brothers and the sister were of a similar body build, varying in weight from 120 (Case 1) to 150 (Case 3) pounds, and from 65 to 67 inches in height, respectively. All had taken active part in athletics during high-school and college days, and appeared to be in excellent health just prior to the onset of their fatal illnesses.

These three unusual cases present a problem in diagnosis and classification. The diagnosis of hypoplasia of the aorta made in Cases 1 and 3 now has been abandoned. Myocarditis was present in Cases 2 and 3 but was not demonstrated in Case 1. The possibility remains that more sections of the myocardium in the latter case might have shown areas of focal myocarditis. Unfortunately, none of the hearts is now available.

It is difficult to avoid the conclusion that some unknown familial myocardial disease was present in each case. The similar clinical course, attacking at a similar age (twenty-three, twenty-six and twenty-five years), lends support to this viewpoint. The presence of complete situs inversus in Case 3 and of a chondroma in the father suggests what Dr. Willius, in a letter to Dr. Hoffman, called "the vicious portrayal of the relentless forces of heredity."

Evans,[1] in a paper entitled "Familial Cardiomegaly," described three cases in one family, and possibly three more unproved ones, with cardiac hypertrophy. Bundle-branch block was present in two, and tachycardia was a frequent occurrence. At necropsy, marked myocardial fibrosis was present in all three. Evans believed his cases might have been related to Friedreich's disease. The cardiac manifestations in Friedreich's ataxia are described in detail by Schilero and associates.[2] Myocardial fibrosis was the commonest finding, and infiltration with lymphocytes and eosinophils was also noted. Occasionally, pericardial effusion, complete heart block, bundle-branch block, valvular involvement as in rheumatic fever, and coronary sclerosis were present. The findings in Evans' three cases and in Cases 2 and 3 of this report are pathologically consistent with the cardiac manifestations in Friedreich's disease.

In the case records of the Massachusetts General Hospital,[3] Case 28042 is that of a man who died at twenty-nine years of age with idiopathic cardiac hypertrophy. His sister and possibly one brother were thought to have the same condition. Complete heart block was present in this case and in the sister. The heart weighed 600 gm. and exhibited enormous dilatation of all the chambers. Aside from hypertrophy, the muscle fibers were normal on microscopic study. A mural thrombus was present in the left auricular appendage. This case resembles Cases 1 and 3 of the present report. Dr. Paul White's comment was pertinent to this discussion. He said, "Each year, at the time of our graduate courses, we try to present one such case as this. It is not only very humbling, but it is also stimulating to our own further studies."

Summary and Conclusions

Three cases of familial cardiopathy are reported. Complete situs inversus was present in one instance. Myocarditis was present in two of these cases but the myocardium in the first case appeared normal. It is postulated that the same familial disease was present in all three cases. Friedreich's disease without the neurologic involvement is a possibility.

Acknowledgments

This series of papers could not have been written without the help of a number of physicians. For permissions and various clinical and pathologic data, I am grateful to Drs. J. Meade, P. Soucheray, E. T. Hermann, J. W. Jesion, C. W. Waas, A. D. Pollack, and G. Mirick. Dr. Kano Ikeda restudied various cases with me and personally prepared all the photomicrographs. Drs. B. J. Clawson and G. E. Fahr gave me valuable advice in the preparation of the manuscript. Dr. O. Saphir restudied the sections in one case. I am deeply grateful to Dr. J. E. Edwards, without whose help this manuscript could not have been written.

Trichinosis, a Declining Infection

FRANKLIN G. WALLACE, Ph.D.,
and ARTHUR J. SANDERS
Minneapolis, Minnesota

A SURVEY was conducted from June 17, 1952, to November 7, 1954, at the Minneapolis Veterans Hospital to determine the incidence of nfection with *Trichinella spiralis*. Portions of diaphragms from 100 autopsies were examined by he compression and digestion methods.

Except for the exclusion of five cases known to have died of tuberculosis, the cases examined for Trichinella were taken at random among the autopsies performed at the hospital, the choice of cases depending only on the authors' work chedule.

Riley and Scheifley[1] in Minneapolis conducted one of the first surveys of Trichinella incidence. Using the compression method they found twenty of 117 cases (17.1 per cent) infected. Scheifley[2] ound fifteen of 118 cases (12.7 per cent) infected n the same city. Numerous surveys in the United States between 1931 and 1942 reveal an incidence of approximately 16 per cent.[3] In San Francisco[4] an incidence of 8 per cent was found in the same city and using the same methods as fifteen years before[5] when 24 per cent were found infected. No statistically significant difference in the composition of the two samples could be shown.

Materials and Methods

Samples of muscular diaphragm were removed by the pathologist. Approximately 90 per cent of he specimens examined weighed between 70 and 80 grams. One sample weighed only 50 grams and the heaviest weighed 165 grams.

One gram of each sample was used for compression examination. Thin portions of teased muscle were compressed between two glass plates and examined for *Trichinella spiralis* larvae under a dissecting microscope or the low power of a compound microscope. The glass plates were held in place between two rectangular brass frames 3½ by 5 cm., and compression was applied by means of two thumb screws. The remainder of the specimen was ground up in a standard household meat chopper. The ground muscle was digested with freshly prepared artificial gastric juice in a 37° C. water bath for a minimum of twenty-four hours with occasional shaking. The artificial gastric juice consisted of 1 per cent pepsin and .25N HCL solution. The suspension was then strained through gauze into a separatory funnel and allowed to stand for a minimum of two hours. Ten ml. of sediment were diluted with distilled water, transferred to a petri dish and examined for *Trichinella spiralis* larvae. Microscopic examinations were done with a stereoscopic dissecting microscope with a magnification of 54 or with a binocular compound microscope using a magnification of 50.

Infected rat muscle was processed on two occasions to verify the effectiveness of the technique.

Results

Of the 100 subjects studied, there was one female and ninety-nine males, one negro and ninety-nine white. Eighty-nine were native-born Americans; the eleven foreign-born came from Austria (one), Canada (one), Finland (two), Germany (two), Norway (two), Russia (one), Scotland (one), and Sweden (one). There was one Jew, nineteen Catholics, and eighty Protestants. Seventy-six were residents of Minnesota, thirteen came from adjoining states, and one from Florida. Eight were farmers, while ninety-two were nonfarm workers or retired.

The age distribution was as follows:

20-29	8
30-39	6
40-49	5
50-59	36
60-69	38
70 and over	7

The two positive cases were males in the 60-69 age group, were nonfarm workers and white, na-

tive born residents of Minnesota. One was Catholic and one Protestant.

Discussion

While the earlier surveys in Minneapolis gave no information on the composition of their samples relative to age, race, religion, et cetera, we conclude that there has been a real decrease in incidence in this area. The difference between the present results and those of Riley and Scheifley[1] is more than five times the standard error, and between present results and those of Scheifley[2] is more than four times the standard error.

Such a marked decrease in the incidence of trichinosis is likely to be attributed to the recently enacted laws (Chap. 355, Minn. Laws 1953, and other laws in neighboring states in the same year) which require the cooking of garbage fed to hogs. It should be pointed out that the present survey was already half completed on July 1, 1953, when the Minnesota law went into effect, and continued for sixteen months thereafter. Trichinella cysts remain alive, or at least visible, for so long in man (variously recorded as thirteen, twenty-four, and thirty-one years by Gould) that the influence of a factor reducing the incidence of the parasite would become evident only after some years. Beard[5] finds that there has been a marked decrease in Trichinella infection in San Francisco in recent years. We believe that there was a marked reduction in Trichinella infection in Minnesota before the garbage cooking law went into effect.

USE OF LIQUID OXYGEN IN DERMATOLOGY

(Continued from Page 152)

is especially valuable in cases which have been treated unsatisfactorily with other measures.

Summary

Liquid oxygen has been a useful agent in the treatment of warts, even though the results are not perfect. In our opinion it is the preferred treatment of the so-called mosaic wart. In our experience it has been also helpful in the treatment of hemangioma simplex and small keloids.

ccidental Gunshot Wounds

W. P. EDER, M.D.
Minneapolis, Minnesota

ENETRATING wounds produced by high velocity missiles have increased in numbers ince the end of World War II. The use of arms by any people during combat has projected itself nto more widespread interest in hunting, skeet and imilar sports. Large numbers of guns of various orts were returned as trophies from battlefronts hroughout the world. The improper care and andling of these weapons has increased the numer of accidental gunshot wounds. In consequence, he physician in areas some distance away from arge medical centers, and simultaneously within hose areas frequented by the greatest number of unters, finds himself more and more often called pon to treat the patient with gunshot wounds.

Types of Gunshot Wounds

Many attempts at classification of gunshot wounds have been made. No classification is enirely satisfactory. The type of missile which inlicted the wound is however of some importance o the physician.

The high caliber, relatively large missile tends o project itself in a relatively straight course. It is nimpeded by most bony structures and will produce rather extensive local trauma adjacent to its ath. Frequently, it will produce a through-and-hrough wound. Such a wound is productive of elatively massive hemorrhage because of the large ocal area which is traumatized. Many patients nflicted with this type of missile survive only a ew moments.

The relatively low velocity, smaller missile has he characteristic of penetrating the initial few nches of the integuments of the human body with ase and then to be rather easily deflected by carilaginous and bony structures and to course along he path of least resistance. Such a missile may wander over great distances, taking a circuitous oute, to imbed itself in either soft tissue or bone with relatively little force. This type of missile roduces very little local trauma because of its ize and velocity. However, because of its erratic ourse it frequently endangers many structures producing relatively widespread damage in comparison to its size.

The small, relatively high velocity pellet produces only minimal damage at the site of its penetration. Damage is relatively great because of the multiplicity of wounds rather than to the individual destruction produced by any one pellet.

Location of the Gunshot Wound

The location of the point of entrance of the missile is of great importance in the management of the patient with a penetrating gunshot wound. Gunshot wounds of the *head* produced by high velocity, relatively large, missiles are almost immediately fatal. In rare instances, the missile may avoid vital centers and the patient may be relatively asymptomatic except for the point of entrance and exit. Low velocity missiles of relatively small caliber frequently enter the calvarium and do not penetrate the opposite side. The missile lies within the substance of the brain. Since the bullet is of relatively low velocity, the local damage is not great. Such patients may have a minimum of neurological signs. When death is not instantaneous, hemorrhage within the brain is the primary problem because of damage to vital centers.

Gunshot wounds of the *face* produce widespread destruction and massive hemorrhage. If death is not instantaneous, the maintenance of an adequate airway become the primary problem. Destruction of the tongue, portions of the pharynx, larynx and trachea may not produce instantaneous death. However, death by asphyxiation within a few minutes may occur because of the massive hemorrhage and obstruction of the airway. Gunshot wounds of the *neck* should be treated as soft tissue injuries unless major vessels or the cervical spine are involved. In this type of injury, maintenance of an adequate airway is imperative in the immediate treatment of the patient.

Gunshot wounds of the *thorax* are of two primary types. When there is injury only of the lung parenchyma, hemorrhage and transient atelectasis are encountered. These, however, are usually self limited and there is adequate time to undertake correction of the hemopneumothorax. When, however, a major vessel has been entered, hemorrhage is massive and death is relatively rapid.

Gunshot wounds of the *abdomen* present the greatest single problem for treatment. In the absence of massive hemorrhage most patients with this type of injury will survive until immediate medical care is available. The multiplicity of organs within the peritoneal cavity makes the definitive treatment extremely difficult. Mortality rate in abdominal gunshot wounds is relatively high. The circuitous course of the missile within the peritoneal cavity makes thorough search of each organ imperative.

Treatment

The general consideration and treatment of gunshot wounds differs in no respect from similar wounds produced by other means. The treatment of shock is, of course, imperative. The maintenance of an adequate airway is always imperative. The use of wide spectrum antibiotics is indicated. Specific treatment may be briefly outlined as follows:

Gunshot Wounds of the Head.—Shock in this type of injury may be of neurogenic origin. The anatomical location of the entrance of the missile may indicate immediate severance of the middle meningeal artery and demand its urgent ligation. In general, supportive therapy is indicated with operative intervention only when there is progression of the coma or neurological findings to indicate increased intracranial pressure.

Gunshot Wounds of the Face.—Maintenance of an adequate airway is imperative. Immediate tracheotomy is often urgently indicated. Control of hemorrhage is important because of the vascularity of the area involved. Careful débridement and primary closure of facial wounds may be left for forty-eight hours while the patient stabilizes. Repair of fractures of the facial bones should be carried out within one week in order to produce the best cosmetic results. Primary reduction of multiple fractures should not be carried out unless the patient's condition has improved remarkably from the initial insult.

Gunshot Wounds of the Neck.—Maintenance of an airway is again imperative. Tracheotomy is often mandatory. Control of hemorrhage is imperative if a major vessel is involved.

Gunshot Wounds of the Thorax.—Primary attention should be centered on adequate respiratory exchange. The presence of a massive pneumothorax should be immediately detected and aspirated. Catheter thoracotomy may be indicated if continued hemorrhage occurs within the pleural space and if the initially reduced tension pneumothorax recurs. It is imperative that the hemothorax be adequately removed in order to prevent a constrictive pleuritis necessitating decortication at a later date.

Gunshot Wounds of the Abdomen.—Exploratory laparotomy is always indicated. In occasional instances, one may feel that the missile has penetrated only through the layers of the anterior abdominal wall in an oblique direction and has not entered the peritoneal cavity. Such patients should be explored. Failure to recognize perforation of an intraperitoneal viscus may lead to the patient's death. Incisions should be large so that the entire peritoneal cavity may be inspected. Perforations of the hollow viscera of the peritoneal cavity are usually in equal numbers since a point of entrance also requires a point of exit. The operator should not satisfy himself that all damaged organs have been adequately repaired until he has followed the gastrointestinal tract from the diaphragm down to the rectosigmoid. The liver, spleen and pancreas should be carefully inspected. The retroperitoneal duodenum must not be overlooked in the exploration. The renal and ureteral areas should be carefully inspected for signs of damage. In most instances, the missle should not be sought after and removed if it is lying in an unaccessible position and in such a position as not to jeopardize the patient's life.

Gunshot Wounds of the Extremities.—In the absence of vascular or neurological findings, gunshot wounds of the extremities represent penetrating wounds of the muscle which require only expectant treatment. Débridement of the point of entrance and exit is carried out to prevent early closure of the wound and to establish adequate drainage. Irrigation of the wound tract is contraindicated. Arterial injuries of the extremities are manifest by massive hemorrhage. Primary repair

Sick People in a Troubled World

HOWARD A. RUSK, M.D.
New York, N. Y.

IMPROVEMENT in the health of the people of the developed parts of the world since 1900 constitutes one of the great achievements of the past half-century. Although some nations of the world still have pressing problems of communicable disease and life expectancy rates vary from nation to nation, the trend in all nations is toward a greatly increasing life expectancy—with the result that throughout the world we are producing an aging population. Medicine's number one problem in the developed areas of the world is no longer the acute, communicable diseases which claimed their victims with dramatic swiftness, but the slow insidious processes of the chronic diseases and the disabilities which they leave in their wake.

Lacking specific measures in the cure of many of the chronic diseases medicine must look to rehabilitation to teach those afflicted by disability to live and to work as effectively as possible. Until medicine finds the specific answers to the problems of the diseases of the heart and circulation, rheumatic fever and arthritis, cerebral palsy, multiple sclerosis, poliomyelitis, and the other crippling diseases, we must utilize the techniques of physical rehabilitation, psychology, social service, vocational counselling, and the para-medical specialties to teach the disabled to live within the limits of their disabilities, but to the full extent of their capacities.

We, as physicians, have a particular stake and a particular responsibility for this problem, for it is one that we have created—created with insulin, liver extract, vitamins, new surgical techniques, sulfonamides, antibiotics, cortisone, and everything else that has gone into making medical care what it is today.

Two thousand years ago, the average length of life was twenty-five years; at the turn of the century, it was forty-nine; recently compiled statistics of the National Office of Vital Statistics show the average length of life in the United States has now increased to sixty-eight. Today, there are more than 28,000,000 Americans who suffer from chronic disease and physical disability. Staggering as this is, we can expect it to increase in the future; for as our population becomes older, the incidence of chronic disease and its resultant physical disability will increase correspondingly.

Until recent years, the great majority of the medical profession looked upon rehabilitation as an extracurricular activity of medicine, something dealing with social work and vocational training, but something which had little concern, which held but few implications, for medicine. Today, however, that trend is being reversed, and although there are still many physicians who are unfamiliar with the aims and procedures of rehabilitation, more and more, medicine is beginning to recognize that medical care cannot be considered complete until the patient with a residual physical disability has been trained "to live and work with what he has left."

The recent tremendous surge of public and professional interest in rehabilitation has not been

CONTRIBUTIONS OF PURE SCIENCE TO PROGRESSIVE MEDICINE

In other words, the great majority of patients seriously ill can be rehabilitated before operation or aided in weathering the storms of readjustment following operation.

Physicochemistry of the human body concerns life itself. A proper understanding of these vital processes is necessary to every man who practices medicine, no matter what his specialty may be; and as for the surgeon, the newer knowledge is changing his outlook. By calling to his aid the scientist, the internist and the various specialists, he is able to bring relief to a large number of patients who formerly were looked on as beyond help, or who, unprepared for operation, were subjected to a high risk. Rehabilitation is to be a master word in medicine.—WM. MAYO, M.D., The Journal of the American Medical Association, 84: no. 20 (May 16) 1925.

Dr. Rusk is Professor and Chairman, Department of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center; President, International Society for the Welfare of Cripples.

This paper is based on an extemporaneous address presented by the author at the Recognition Exercises honoring the Senior Class in Medicine, University of Minnesota Medical School, June 10, 1955.

limited to the United States. Great Britain and the Northern European nations, faced as we are in this nation with a striking increase in chronic disability resulting from the extension of the life span, have long recognized the medical, social and economic values of rehabilitation.

This interest now, however, is being seen in Latin America, the Near East, Southern Europe, and Asia, in those parts of the world commonly termed "underdeveloped." In some of these nations, rehabilitation services are provided by voluntary groups which are national affiliates of the International Society for the Welfare of Cripples. In others, the national or local governments have built the facilities and operate the programs.

This spring, a new Rehabilitation Institute for the Blind was opened in Mexico City. An important part in its planning was played by an American specialist from the Office of Vocational Rehabilitation, which has been in Mexico the past three years under the Institute of Inter-American Affairs, helping the Mexican government organize services for the handicapped.

The International Society for the Welfare of Cripples' affiliate in Lebanon is developing a rehabilitation program for children in Beirut which will be affiliated with the Pediatrics Department of American University. The World Health Organization is providing personnel and the United Nations International Children's Fund equipment for the new center.

In Korea, the Republic of Korea, the United Nations Korean Reconstruction Agency and the American-Korean Foundation teamed together two years ago to open a 300-bed National Rehabilitation Center at Tongnae, just outside of Pusan.

These developments over the world did not just happen. Behind them, particularly in the so-called "underdeveloped areas" of the world there is beginning to emerge a new concept of the dignity of man and the value of the worth of the individual that is being symbolized and expressed in the development of rehabilitation services for the handicapped.

Just as our own favorable geographical, political, economic, cultural and social circumstances have placed the United States in a position of world leadership and responsibility in so many other fields of endeavor, we bear a special responsibility globally in the development of rehabilitation services to the handicapped. But in accepting this responsibility, we are serving more than high idealistic, moral and humanitarian ends.

Peace is never a product of military force alone. Nearly ten years of the cold war have taught us that political health of our own nation and of the world depends on the physical and mental health of our people.

Today through the World Health Organization, the United Nations, our own Foreign Operations Administration and various international voluntary organizations, we have tangible and specific methods through health for building strong allies and true friends.

Experience has long shown that rehabilitation services for the disabled is a purchasable commodity. Today the world now has the technical knowledge and skills to bring improved rehabilitation services to the disabled no matter where they live. Results can be anticipated almost in direct ratio to the efforts and funds expended.

Aside from the political and economic significance of improving the health of the people of the world, rehabilitation can also provide the understanding between peoples and nations that is the essential foundation of any political effort toward peace. This has been brought forcibly home to me during the past few years when I have had increased opportunities for personal travel and have seen directly the results which can be achieved in international understanding through rehabilitation and services to the handicapped.

Last September at The Hague, for example, at the Sixth World Congress of the International Society for the Welfare of Cripples, there were 800 delegates from thirty nations. Physicians, nurses government officials, employers, therapists and interested citizens, they had one common interest—how services for the disabled in their own nations and globally could be improved and extended.

They came mostly at their own expense because of their desire to learn and to share their experiences and knowledge with others.

Two unmistakable facts emerged from the meeting. The first—and very encouraging—is that rehabilitation services for the disabled are increasing rapidly throughout the world. The second—and equally discouraging—is that the number of persons needing such services is increasing more rapidly.

A part of the increasing incidence of physical disability found in the developed parts of the world results from the lengthening of the life span through medical advances, better public health and improved living standards.

Persons who a few decades ago would have died from acute communicable diseases now live and in their later years acquire such crippling afflictions as arthritis, multiple sclerosis and Parkinson's disease, or they suffer strokes.

Similarly each year, medical advances are made that prevent death but leave survivors with severe disabilities. Each represents a precious human life saved, but it raises the question of whether the society that can save a life can also, through rehabilitation, give that life dignity, purpose and meaning.

Never before in human history have our opportunities for reaching this objective of lives of dignity, purpose and meaning for the disabled been as great. Today, we can approach with confidence many disabling conditions which, even as recently as twenty years ago, were generally accepted as hopeless. But the greatest of these assets is not the skill of the surgeon, the wonders of antibiotics, or modern techniques of selective placement—our greatest assets are these patients themselves.

When I was in Poland in 1949, I went through a concentration camp in Auswich, the largest one there. In a room half the size of this large center section, the first thing one saw was a bin filled with braces and crutches and canes and prosthetic devices, because the cripples were the first who went to the gas chamber. Hitler forgot that that was the spirit of Germany. The Communists forgot in 1950, and most of us forgot that it happened.

The year before the Communists marched down into South Korea, they drove across the thirty-eighth parallel a million people—the old, the halt, the sick, the lame, and the blind—feeling that if they put this load on the staggering economy, it would cause it to fail. It had just the opposite effect. It gave the South Koreans strength that they didn't know it was possible to have. Refugees were taken in, the food was shared, the warmth was shared, the clothing was shared. And it became a part of the great spiritual strength that has allowed this little country to lose more people than we lost in World War I, World War II and the Korean War put together, times two, and still ask for the privilege of continuing to fight to be free.

In our planning for the future of such persons, we have too frequently operated under the fallacious concept of generations ago that success and ability to do a given job was dependent upon physical strength. This, however, has not been true since the days of the cave men, and most of us today use less than 25 per cent of our physical capacities in daily living. The great single asset in our work, however, is still the patient and the tremendous powers of recuperation and compensation which the patient possesses.

The blind man, for example, has lost his sight, but he has compensated for that loss by overdeveloping his senses of touch and hearing, for this is the way he now sees. He carries the white cane and taps it because his ears are so acutely attuned that he can tell whether the echo coming back is from a wall or from an area of trees or if he is in an open space. Put the blind man to work in a photographic darkroom or in his own environment and he will turn out 30 per cent more work than the man with sight who is working by his side.

Society today pays for only two things: what we have in our heads and the skill in our hands. But compared with the average, so-called "normal" person, the person with a severe physical disability often has another asset in far greater supply than we have—that is their depth of spirit.

Of the various phases of international health endeavors there is none today in which the efforts of all—both governmental and voluntary—have been more closely integrated than in rehabilitation. It is not surprising that we have and are achieving this high degree of co-operation in our work for the handicapped where, in many instances, those concerned with other forms of human relationships have failed.

I have tried to state these reasons in a short statement which I prepared some time ago for Edward R. Murrow's program, "This I Believe." I would like to close by reading this statement for it is my own philosophy about "Sick People in a Troubled World."

"I can't remember when I didn't want to be a doctor. Even as an adolescent when I scrubbed floors and ran errands at the local hospital in order to smell ether and go on rounds with the country doctor, surgery did not spell the glamour in medicine to me. It was people—sick people—their suffering, their problems and their victories that challenged.

"It has been a rare privilege to be a doctor in medicine's golden era. Far more scientific advances have been made in the last three decades than in all time heretofore. Man's life span has increased from eighteen two thousand years ago to sixty-eight in America today.

"But I have found it impossible to ignore the fact that these great medical advances have posed new problems. Crippled children who in the past would have died early in life now survive. They want to grow and work and love and be loved.

"I have heard old people to whom we have added these years ask, 'For what—the shelf to wait for death, or an opportunity to live and work in dignity as long as we are able?'

"Millions of veterans throughout the world who have scarred their minds and given parts of their bodies to war have more than earned their right to live and love and work and to know that their sacrifice has at least been one small stone that is being used to build a better world.

"Sick people throughout the world ask their God, 'Why must I suffer?' Possibly the answer comes in the work of the potter. Great ceramics are not made by putting clay in the sun; they come only from the white heat of the kiln. In the firing process, some pieces are broken, but those that survive the heat are transformed from clay into objects of art, and so it is, it seems to me, with sick, suffering and crippled people. Those who, through medical skill, opportunity, work and courage, survive their illness or overcome their handicap and take their places back in the world have a depth of spirit that you and I can hardly measure. They haven't wasted their pain.

"Because of this experience, they have a desire to share that is almost a compulsion. It matters not whether they be a physician from India, a Zionist from Israel, a Greek veteran or a Pole disabled in a mining accident—all want to share the understanding they have gained through suffering or by helping those who have suffered.

"I believe that this basic and inherent desire of man to do something for his less fortunate fellow transcends religious dogmas, political beliefs and geographical barriers. If we could only use this universal language, we would have a tool to unravel the babel of tongues and an instrument which would penetrate any iron curtain or closed boundary.

"It does not seem strange to me that the sick should turn to those who have suffered for their greatest comfort. And so, in a sick world, it is not strange that we turn to those who have been ravaged by suffering and disease for a common language. If we could start to work here together in a program where all of us have the same goals, it is more than possible that, with God's help, we would find the solution for living together in peace. This I Believe!"

TREATMENT OF SEVERE INJURIES OF THE HAND

(Continued from Page 150)

will insure the successful outcome of treatment of hand injuries. Bunnell has said that one cannot fix a watch in the bottom of a bottle of ink. Similarly, we are handicapping ourselves in operating on the small structures of the hand if our field of vision is occluded by blood. Major hand surgery should be accomplished on a dry operating field maintained by pneumatic tourniquet. Then again, we cannot do fine work with large instruments designed for abdominal or large extremity work. Large instruments may cause increased trauma to tissue and clumsiness in repair. We must not jeopardize our work by not having the right equipment and the right operating conditions.

Boyes suggested that we give 10 points to each element—the material, the principle and the technique—and that our "batting average" would then be equal to the product, not the sum, of our rating in each of these sections. It can be seen then that we can drop only a few points in each component before our average will fall off precipitously. If we are going to do the best that we can to prevent serious crippling in the severely injured hands that come to our care, we must not be confused about the anatomy, must not make poor decisions as to what needs to be done, and must not handicap ourselves with inadequate instruments or poor working conditions.

Medicine in Southern Minnesota

DAVID P. ANDERSON, M.D.
Austin, Minnesota

IT is a prerogative of the president of the Southern Minnesota Medical Association to deliver an address on a subject of his own choosing. I prefer to confine my remarks to matters close at hand. This, then, will be somewhat of a "State of the Union" address on medicine in southern Minnesota.

I think it is obvious to all of us that the state of the union is good. Good medicine is practiced in southern Minnesota. Good medical practice is moving to the small communities, and our section of the country has made progress, in this respect, that far surpasses the tremendous general progress in medicine during the past decade. I invite any disbelievers to make rounds with us in our small community hospitals.

There are many intricately interwoven reasons to explain our gratifying progress. I will mention a few, simply that we may pause for a while to count our blessings.

An influx of well-trained young men, both specialists and much-needed general practitioners, has certainly been a healthy stimulus in recent years. The middle-aged and older physicians that I know have accepted this challenge of young competitors by utilizing any special knowledge of their young colleagues advantageously, while still competing forcefully in the only way that really counts; namely, by giving their patients *good* medical care. This, too, has created a healthy situation, for wisdom gained by experience and refreshed by a continuous search for knowledge is hard to beat.

Without wishing to slight my other fellow specialists, I would like to point out that the present availability of x-ray specialists has been a particularly valuable addition to our small communities. It is hard to conceive of practicing medicine without a roentgenologist handy, isn't it! And yet only a few years ago you could hardly find one anywhere. Incidentally, I secretly envy these fellows: They do not have to compete with anyone, except the occasional patient with poor and sphincter control. They can live in the midst of the crowd and keep with perfect sweetness the independence of solitude.

It seems almost superfulous to mention the favorable influence of our two large, nearby medical centers upon medical practice in our area, and yet we must never forget our geographically favorable position. Where else can an ordinary country surgeon pick up a telephone and, for a few cents and on a first-name basis, get the gracious assistance of any number of the world's best consultants? I never feel belittled by asking for such help when I need it. On the other hand, I have no intention of being overwhelmed by the competition or misled into the debilitating practice of dumping all my tough problems in someone else's lap.

We are also grateful for the advantages in postgraduate education which are offered by the proximity of our medical centers and by the continued efforts of the directors of these centers to make their teaching facilities available to us. We should make the most of our opportunities.

One cannot fail to recognize the fact that a favorable economy and the rapidly increasing coverage of our population with voluntary health insurance plans have been big factors in the improved medical care which we are now enjoying. Health is no longer much neglected for financial reasons.

It is regretable that a few patients, hospital administrators and physicians have abused insurance coverage, at least in principle, even though they may be within the limits set forth in the fine print. This practice is not widespread—I would say that 99 per cent of us lean over backwards to be fair and honest to both the patient and the insurance carrier. It is hard to deliniate a clear line of cleavage between the many essential x-rays and other diagnostic studies that are demanded by medical science and the modern charlantry of diagnosis by exhaustive tests. Certainly the problem patient deserves "the works," but when every patient be-

---

Presidential address delivered at the annual meeting of the Southern Minnesota Medical Association, Albert Lea, September 12, 1955.

comes a problem patient, one's colleagues begin to wonder. I suspect that a mixture, in unknown proportions, of a subconscious appreciation of one's own ignorance, avarice and just plain laziness motivates the offenders. I also suspect that these offenders do not appreciate the fact that they are easily spotted by their colleagues, nor do they seem to realize that they are a cancerous growth that could kill the health-insured goose that lays such nice golden eggs. The fact that seemingly intelligent patients continue to return to them and that they occasionally unearth a surprise diagnosis would seem to be poor compensation for the practice of bad medicine disguised by good x-ray and laboratory tests.

Now that I have slipped over into a somewhat critical attitude, I should like to continue along this line for a brief time. Before doing so, I would like to reiterate that the practice of medicine in southern Minnesota is good—very good. Under such circumstances one can be sharply critical without fear of offending too many people. It's a good time, though, to evaluate our own faults, while they are few in number and easily erradicated.

There has been a great deal—in fact, too much—said and written about the evils of unnecessary surgery and fee-splitting in recent years. The problem is almost non-existent with us, I am sure, but let us continue to be frankly and openly disapproving of any offenders. Let us be honest with ourselves in evaluating our own surgery: it's the hardest thing in the world to do, I know, for a general surgeon to decide what *not* to do. The problem must be even more difficult for the general practitioner doing some general surgery. I know there are many general practitioners who do quite acceptable major surgery, and I personally see no reason for specialty groups to attempt to arbitrarily limit them; the honest practitioner will limit himself. The greatest of faults, though, is to be conscious of none, and this creates the greatest of surgical problems, or perhaps I should say, the greatest "problem surgeons": how does one limit the man who is doing surgery he has no business doing? I know of no good answer, unless it be that we so continuously expose such men to the disease of intellectual honesty that they eventually catch it.

One final thought. The doctor is constantly being drafted, often too willingly, for civic activities of all types. I know that we physicians have been criticized for failure to uphold our civic duties and that we have definite obligations to our communities, churches, service clubs and many worthy causes; but I would like to interject a small word of caution: this thing can be overdone. Somewhere along the line, if one has too many civic commitments to fulfill with promptness and efficiency, patients are sure to be neglected.

"The physician lives not for himself but for others. This is the essence of his profession. Do not look for fame or profit. Work to save others though you lose yourself. Maintain life, restore the sick and ease the suffering of man. You have no other object."

ESOPHAGEAL HIATUS HERNIA

(Continued from Page 143)

included a right pneumothorax in one patient, and the thromboembolic episodes in two.

One patient died of a myocardial infarction two months postoperatively. Though his preoperative electrocardiogram was negative, one wonders in retrospect whether his coronary disease rather than his hernia was responsible for his pain. The remainder of the patients are living and well, and there has been no evidence of recurrence of any of the hernias. One patient, an intensely conscientious executive, has had a return of some vague gastrointestinal symptoms, but a recheck x-ray examination is negative. The rest of the patients are asymptomatic.

In conclusion, we feel that many people with vague upper abdominal complaints should be studied with hiatal hernia in mind; if the defect is present, well-planned treatment will usually relieve the patient of his symptoms.

Case Presentations

Henoch-Schoenlein's Purpura

JOHN T. OLIVE, M.D., and
CHESTER E. THIEM, M.D.
Mankato, Minnesota

HENOCH-SCHOENLEIN'S purpura is a generalized disease consisting of a characteristic skin lesion and found associated with joint symptoms, gastrointestinal colic and bleeding, with swelling of the face, extremities, and scrotum. The skin lesion, progressing from urticaria to typical purpura, is the prime feature of the disease. It may be associated with any or all of the other symptoms.

In 1837, Schoenlein[1] recognized the combination of rash with joint symptoms as related and named it "peliosis rheumatica." In 1874 Henoch[2] described the disease in four children and noted the association with hematuria. Osler[3] was especially interested in these cases and felt that the symptoms were manifestations of an anaphylactic phenomena. He wrote: "The anaphylactic key will unlock the mystery of these cases." In 1948 Gairdner[4] showed that both infection and hypersensitivity were involved. Lewis[5] has compared this disease with nephritis and rheumatic fever and concluded that they may have a similar etiology.

The following case report is of interest because it illustrates the characteristic features of the disease.

Report of a Case

A boy, eight years of age, was admitted to the hospital because of fever and a sore throat of three days' duration. He had had two previous episodes of severe sore throat, during one of which it was feared that a tracheostomy would have to be done. However, he had recovered fully from both attacks. He had had uncomplicated measles and chicken pox. His past health had otherwise been good. His growth and development were normal. He was an only child of healthy parents.

Physical examination revealed a severe follicular tonsillitis surrounded by an inflamed, edematous area covered by a whitish, purulent, exudate. He had tender and enlarged cervical lymph glands and complained of severe pain with swallowing. His temperature was 102° F. Examination was otherwise normal.

Laboratory examination revealed a normal urinalysis; the hemoglobin was 12.8 gm., and the leukocyte count was 11,950 per cu. mm.; B hemolytic streptococcus was cultured from the throat.

He was given an adequate dosage of oxytetracycline and saline irrigations of the throat. The following day he was much improved. His temperature was normal and he was able to eat and drink without pain. On the third hospital day he developed painful swelling of his knees, wrists, elbows, and ankles. His temperature rose to 100° F. and his Sedimentation Rate was 33 mm. (Westergren). An electrocardiogram showed an increased P-R interval. A diagnosis of rheumatic fever was made and a course of salicylates was started using aspirin in adequate dosage. On the fifth hospital day the boy showed no improvement and it was decided to discontinue aspirin in favor of cortisone. While on cortisone, the boy showed some improvement with less pain and swelling of the involved joints. On the ninth hospital day he suddenly developed marked edema of the face, extremities, penis, and scrotum. Cortisone was discontinued with the thought that edema was due to sodium retention. During the next two days the edema of the extremities disappeared, but continued in the face, scrotum, and penis. On the eleventh hospital day a fine purpuric rash appeared over his ankles, knees, arms, and buttocks. He began complaining of severe abdominal and chest pain. Upon examination his abdomen was rigid, very tender to palpation, and simulated an acute peritonitis. Laboratory findings included gross hematuria, Grade III albuminuria, sedimentation rate of 40 mm. per hour, normal platelet counts, normal blood urea nitrogen, and a normal bleeding and clotting time. The Rumpell-Leeds test was positive showing 15 to 20 petechiae per square inch on the left arm. These findings occurred concurrently with the appearance of purpura.

The boy then gradually improved. On his fourteenth hospital day the urine revealed microscopically Grade I hematuria and the albuminuria had disappeared. The areas of purpura were fading and the edema of the face and genitalia was almost gone. It was decided to send him home for further treatment consisting only of bed rest and a low salt diet.

During the following two weeks at home, he developed several transient areas of purpura on his trunk and extremities and also had intermittent severe abdominal

---

Presented at the annual meeting of the Southern Minnesota Medical Association, Albert Lea, September 12, 1955.

and chest pain which required codeine for relief. During the third week at home, the boy developed persistent bloody stools and was readmitted to the hospital. Examination at this time revealed no purpura, swelling, or joint pain. Laboratory investigation revealed a normal urinalysis, hemoglobin of 12.4 gm., 4.85 million erythrocytes per cu. mm. and a sedimentation rate of 26 mm. per hour (Westergren). During the next two hospital days the bloody stools subsided and he was again discharged.

During the next month bed rest was continued at home and he had no recurrence of his symptoms. His sedimentation rate gradually fell to normal. He was gradually returning to full activity over a three-month period and has not had an exacerbation to this date, six months after his original episode.

Comment

This patient exhibited all of the features of Henoch-Schoenlein's purpura. Infection of the throat with B hemolytic streptococci was followed by the typical complex of: purpura, arthritis, swelling of the extremities, abdominal pain with bloody stools, and hematuria. These symptoms were intermittent for a period of one month.

The etiology of Henoch-Schoenlein's purpura is unknown. However, it may belong to the group of diseases which represent a state of hypersensitivity and are known as the "collagen diseases." The hypersensitivity may be either bacterial, following B hemolytic streptococcus infection, or nonbacterial, following exposure to specific protein antigens. Sir William Osler[3] first made note of this and it has since been called "anaphylactoid purpura." Occasionally it occurs concurrently with rheumatic fever.[4] The hematuria that occurs is indistinguishable from that of acute nephritis[6] and is associated with albuminuria, cylinduria, and rarely a hypertension.

The purpura is the differentiating factor, without which the diagnosis cannot be made. Gairdner[4] has described in detail the pathogenesis of these lesions and has shown a progression from simple urticaria through a maculopapular eruption to typical purpuric lesions. The purpura may be associated with one or all of the previously mentioned findings. The platelets are normal in number and the bleeding and clotting time are usually normal. The Rumpell-Leeds test may also be positive.

Henoch-Schoenlein's purpura is primarily a disease of children; it has its highest incidence at three years of age. It occurs more commonly in males than in females. The duration of the initial phase may be from three weeks to six months. Relapses of the purpura are common.

The abdominal pain, which often initiates the onset of the disease, may be very severe and simulate an acute abdominal emergency. It is for this reason many of these cases have exploratory laparotomies performed before the true nature of the disease is ascertained.

In this case the acute nephritis was of short duration, lasting only a few days. Some, however, are not so fortunate and develop into a chronic or latent nephritis. Wedgewood[7] describes ten children of a series of twenty-six that had abnormal urinary findings several months after the initial attack. This appears to be more common in the child over six years and also those who have had several relapses of the disease.

Treatment of our case was confined to bed rest. Recently some authorities[8] have used cortisone and adrenocorticotropic hormone during the acute phase of the disease. They feel that the course of the disease is not significantly shortened and it does not prevent the urinary complications.

Continuation Studies

Infectious and Postinfectious Encephalitis

PAUL M. ELLWOOD, JR., M.D.
Minneapolis, Minnesota

THIS paper deals only with the infectious, postinfectious and post-vaccination encephalitides which occur with reasonable frequency in the Minnesota area. It is our opinion that with the increased use of the poliomyelitis vaccine these various encephalitides will become of increasing importance as a diagnostic consideration in patients manifesting symptoms of encephalitis.

Primary Encephalitis

The primary encephalitides are presumably due to direct invasion of the central nervous system by viruses pathologically producing neuronal destruction in the brain and spinal cord and commonly a syndrone of fever, headache, stiff neck and pleocytosis. With the advent of modern tissue culture techniques for the diagnosis of poliomyelitis, an attempt has been made at Elizabeth Kenny Institute to make an etiological diagnosis of all patients referred to the Institute as nonparalytic poliomyelitis with the above symptom complex. Poliomyelitis virus isolation and antibody studies were carried out by Dr. Jerome T. Syverton of the Bacteriology Department, University of Minnesota, and antibody studies for other viral encephalitides by the Communicable Disease Laboratory of the Minnesota Department of Health under the direction of Dr. Henry Bauer. Diseases are listed in the frequency in which they were encountered at Elizabeth Kenny Institute during 1954 and 1955.

Poliomyelitis.—This disease is due to three antigenically distinct viruses, each one capable of producing the same clinical symptomatology. The disease is apparently disseminated from person to person. The most commonly quoted incubation period is approximately fourteen days, but the virus is known to remain in the stools up to three or four months after onset. Poliomyelitis follows a biphasic course, especially in children, the first phase of which is nonspecific. The secondary phase affects the central nervous system with fever generally lasting five days. Scattered lower motor neuron palsies, which occur during the course of the febrile illness and when present in the absence of sensory changes, are diagnostic.

Nonparalytic poliomyelitis, in our experience, has been clinically indistinguishable from most of the other viral encephalitides. Prognosis with poliomyelitis is, of course, highly variable, but with nonparalytic poliomyelitis is excellent.

Mumps Meningoencephalitis.—Mumps virus has been isolated from the central nervous system on numerous occasions. Mumps meningoencephalitis is a very common disease reported to occur is up to 30 per cent of cases of parotitis. The symptoms of encephalitis generally follow those of parotitis but can precede or occur in the absence of visceral involvement. The disease usually runs a benign course with minimal disturbance of sensorium or evidence of neuronal involvement. A rare, yet characteristic, complication is involvement of the VIII cranial nerve producing vomiting, vertigo and deafness. This disease is one of the most benign of the viral encephalitides.

Lymphocytic Choriomeningitis.—Lymphocytic choriomeningitis, due to a virus found in lower animals and generally transmitted to man from the infected excreta of mice, is more common in the winter months but cases have been reported in Minnesota in every month of the year. The incubation period in the experimental infection in man is from twenty-four to seventy-two hours. The disease produces a very diverse clinical pic-

From the Departments of Pediatrics and Neurology, University of Minnesota, and Elizabeth Kenny Institute, Minneapolis, Minnesota.

ture. Fever often is bi- or triphasic; respiratory symptoms in the pre-central nervous system stage of the disease are the unique feature. Fever in most cases lasts five days and while the course is often benign, coma, paralysis and post-encephalitic Parkinsonism have been reported. Complications of this type notwithstanding, the prognosis is in most cases good.

TABLE 1. TYPICAL FINDINGS IN LABORATORY DIAGNOSIS OF VIRAL ENCEPHALITIDES

Disease	*Cerebrospinal Fluid*			*Diagnostic Tests*
	Cells	Sugar	Protein	
Poliomyelitis	Mean 56 0-1000	Normal	46 mg.% 20-150 mg.%	Neut. antibody rise within 2 wks. *Virus isolation from feces
Mumps	Mean 400 9-1700	Normal	Normal	C-F antibody rise in 10 days
Lymphocytic Choriomeningitis	Mean 700 0-6000	Occas. Low	Gen. Elev. 15-300 mg.%	*C-F antibody rise in 15-30 days Neut. antibody rise in 60-180 days Virus isolation from CS fluid
Coxsackie	Mean 20 6-200	Normal	Normal	Virus isolation from feces

**Best diagnostic technique*

Coxsackie.—There is a reasonable amount of evidence to incriminate the B group of Coxsackie virus with encephalitis. These viruses have been isolated along with polio viruses in many known cases of poliomyelitis at Elizabeth Kenny Institute. The most frequently described clinical picture is herpangina and myalgia associated with symptoms of meningeal irritation and fever. There have been no sequelae and no fatalities among our cases.

Western Equine and St. Louis Encephalitis.—The mosquito is known to be the vector, but the true reservoirs of infection are not definitely known. The incubation period is highly variable, being from five to twenty-one days. Arthropod-borne encephalitides, like so many other members of this group, cannot be differentiated clinically but the clinical features of the disease vary greatly with the age of the patient. The disease is far more severe in infants under one year of age than in older children and adults. Convulsions and drowsiness are common in infants. This disease can be transmitted to the fetus from an infected mother. The most common sequelae are convulsions, behavioral disturbances and upper motor neuron signs. Sequelae have been reported to occur in up to 50 per cent of children under one year of age to a low of 20 per cent in children between the ages of five and fourteen.

Encephalitis of Undetermined Etiology.—At least 10 per cent of the patients referred to Kenny Institute with fever, headache and pleocytosis have been undiagnosable by existing techniques and apparently represent infections due to as yet undiscovered infectious agents.

Laboratory Diagnosis.—Table I shows the typical spinal fluid findings in the viral encephalitides and also lists the diagnostic tests which have been found to be useful in making a definitive laboratory diagnosis. Most of these diseases have spinal fluid cell counts which fall between the range of 50 and 250 and therefore provide little help in the actual diagnosis. Lymphocytic Choriomeningitis, however, often has a very high cell count of a mononuclear type which is highly suggestive of this diagnosis. The differentiation of lymphocytic choriomeningitis from tuberculous and other bacterial meningitides is occasionally complicated by the fact that spinal fluid sugars are sometimes abnormally low in this disease.

Secondary Forms of Encephalitis

These forms of encephalitis follow especially the xanthematous virus diseases and vaccination against smallpox. Their exact etiology is unknown, the prevailing theories being (1) direct invasion of the central nervous system by viruses, (2) activation of a second virus already present in the central nervous system, (3) damage to the central nervous system by toxic products of the viral infections, and (4) an antigen antibody reaction.

Post-Viral Encephalitides

The post-viral encephalitides are usually more severe than the primary viral encephalitides. Direct destruction of neurons is unusual, but extensive myelin destruction adjacent to blood vessels is the most common pathological manifestation.

Measles Encephalitis.—The incidence of measles encephalitis varies with the epidemic, the usual case rate being one case of encephalitis to 1,000 cases of measles. Measles, when modified by gamma globulin, or when prevented, is rarely followed by encephalitis. The acute phase of the disease lasts approximately a week with stupor, convulsions and upper motor neuron signs being commonly reported as the early symptoms. These symptoms usually appear within five days after the appearance of the skin eruption but have been reported as appearing during the prodrome and as long as ten days after the skin eruption. Children manifesting extremely severe symptomatology in the acute phase of this disease often recover to a remarkable extent. Shaw reports in an article in the *Journal of Pediatrics* that one-third succumb, one-third recover with severe sequelae and one-third are normal and have minimal sequelae.

Varicella Encephalitis.—Chickenpox encephalitis generally follows skin eruption by three to eight days; its occurrence seems unrelated to the severity of varicella. The disease is much less common than measles encephalitis although the early symptomatology is quite similar. Ataxia and cerebellar symptomatology have been noted in a larger percentage of cases than in any other form of encephalitis. Age seems to bear no relationship to prognosis in this form of encephalitis. Convulsions are an ominious prognostic sign. The prognosis is somewhat better than measles, both acutely and in terms of sequelae.

Smallpox-Vaccination Encephalitis.—The highest reported incidence in all age groups is 1:5000. The disease is extremely rare in infants under one year of age. Some series quote a rate as low as 1:800,000. Symptoms generally appear ten to fourteen days after the vaccination with the disease following a hyperacute course; hyperthermia, coma and respiratory and cardiovascular complications are quite common. The mortality rate from post-smallpox vaccination encephalomyelitis is high—between 35 and 60 per cent.

Post-Bacterial Encephalitides

The pathogenesis of these diseases is very poorly understood. The actual pathological manifestations differ from the post-viral encephalitides in that there is often extensive endarteritis, perivascular bleeding and neuronal destruction. As a group they represent one of the more severe forms of encephalitis.

Post-Pertussis Encephalitis.—While the pathogenesis of post-pertussis encephalitis is not understood, it is observed often to begin after a paroxysm of coughing. This variety is much more common in the very young and produces severe motor and medullary disturbances, as well as mental retardation. According to Livingston in *The Diagnosis and Treatment of Convulsive Disorders in Children,* this disease is the most common cause of post-encephalitic convulsive disorders despite the wide use of pertussis vaccination.

Post-Pertussis Vaccination Encephalitis. — The symptoms of this variety of encephalitis occur from one hour to one-and-a-half days after the injection of pertussis vaccine. Livingston, in his monograph on convulsive disorders in children, which covers a study of approximately 7,000 children with recurrent convulsions, seriously questions whether children with convulsive disorders or convulsive tendencies are any more likely to develop cerebral complications from pertussis immunizations than are other children. The onset of post-pertussis vaccination encephalitis is explosive with the most common symptoms being fever, convulsions and motor disturbances. Prognosis is not good for those cases manifesting motor symptoms and recurrent convulsions which may gradually clear up over a period of many months, or persist indefinitely.

Scarlet Fever and Rheumatic Fever.—Encephalitis, excluding Sydenham's chorea, accompanies rheumatic fever more commonly than scarlet fever in which it occurs in two cases in 10,000. It is characterized by many more behavorial disturbances than the other forms of encephalitis; acute delirious mania and extreme psychomotor activity, accompanied by choreiform movements and incoordination, are the common symptom complex. The mortality rate is reported to be 15 per cent, 40 per cent having permanent sequelae especially in the form of behavioral disturbances.

Treatment

The treatment of the diseases described above is almost entirely prophylactic and symptomatic. The important factor in the treatment is to anticipate involvement of the vital structures by heeding such warnings as facial palsies which generally precede involvement of medullary respiratory and cardiovascular centers and shoulder musculature involvement which often precedes paralysis of muscles of respiration. Conflicting reports have appeared concerning the therapeutic value of ACTH and cortisone in the post-infectious encephalitides. These agents are contraindicated in the primary viral encephalitides with the possible exception of mumps.

Sedatives should be used only with great care, especially respiratory depressants such as morphine and barbiturates.

Respiratory Management.—Respiratory insufficiency secondary to airway obstruction and respiratory infections is the most common cause of death in these diseases.

Airway obstruction can be prevented through the use of postural drainage and frequent suctioning. In rare instances, tracheotomy may be necessary. The value of intubation in emergency cannot be overemphasized.

Infection can be prevented through frequent turning, pounding of the chest, humidity, expectorants and prophylactic antibiotics.

Respiratory paralysis requires use of the respirator. If none is available, "bag breathe" with an anesthesia machine. If respiratory paralysis is due to involvement of the respiratory center with sparing of the muscles of respiration, curare can be used to relax the patient in the respirator.

Vascular Insufficiency.—Rule out the possibility of respiratory induced shock and heart failure. Cardiovascular centers are rarely involved. Norepinephrine should be used cautiously to avoid gangrene at intravenous site.

Feedings and Fluids.—Intravenous feedings are desirable initially to avoid possibility of aspiration. Effort should be made to avoid over-hydration with possible aggravation of cerebral edema. Great care should be exercised in administering gastric feedings containing too high a solute load to comatose patients because of the danger of producing dehydration, hyperchloremia and azotemia. Gastric hemorrhage and perforation are relatively common complications and can be prevented by the instillation of cream and antacids.

Prevention of Deformities.—Extremities should be put through a full range of motion several times daily to prevent deformities. We have also found hot packs to be useful in relieving pain and muscle spasm.

Hyperthermia.—Hyperthermia is the common cause of death in patients with encephalitis, apparently due to involvement of the hypothalmus. When aspirin fails to lower temperature, it is highly suggestive of disturbance of the temperature-regulating mechanism and is a signal for the most vigorous efforts to lower temperature, especially by lowering the environmental temperature.

Conclusions

This paper presents a brief review of the more common forms of encephalitis which are seen in infants and children in this region. A résumé of the treatment of these diseases is also presented.

Current Concepts

HYPOTENSIVE DRUGS

WALTER F. KVALE, M.D.
Rochester, Minnesota

The number of drugs used in the treatment of essential hypertension has multiplied rapidly in the past three years. Despite use of many names, the four basic agents are (1) Rauwolfia serpentina, (2) Veratrum viride, (3) hydralazine hydrochloride and (4) the ganglion-blocking agents, hexamethonium and pentapyrrolidinium bitartrate. Contrary to the usual advertisement, treatment of essential hypertension is often difficult. However, many patients with essential hypertension can be treated successfully by use of one or more of these basic agents.

All these drugs have effects other than hypotensive. These effects may be minimal to severe and transient to persistent; every physician who treats essential hypertension should be familiar with them, as should the patient. The effectiveness of any hypotensive drug cannot be predicted. Thus, a trial of treatment is important. If one drug fails, another agent or a combination of drugs should be tried.

Rauwolfia serpentina is usually safe and easy to administer. Troublesome side effects are infrequent; they include nasal stuffiness, sedation, mild bradycardia, laxation and, at times, nightmares and agitated depression. The hypotensive effect of Rauwolfia may not appear for several days or weeks, as it is not a potent hypotensor. It is most effective in mild, labile hypertension and less so in severe hypertension. It characteristically induces a feeling of tranquility and well-being, without somnolence. Reduction in blood pressure is gradually induced and smoothly maintained. The drug is usually administered four times a day; after six to eight weeks, one or two tablets a day may suffice. Severe depression may occur with long-continued use.

Veratrum acts rapidly. The hypotensive effect begins about one-half hour after a single oral dose, reaching a peak in about two hours and diminishing over the next five to eight hours. Initially, a small dose is given after each meal and at bedtime. Each dose is gradually increased until satisfactory reduction of blood pressure is achieved or undesirable side effects occur. These effects are epigastric burning and hypotensive crisis, with increased salivation, hiccup, vomiting, bradycardia and circulatory collapse; they can be abolished by intravenous injection of atropine sulfate (1/120 to 1/60 grain). Results from preparations of Veratrum are unpredictable. Many patients cannot tolerate them in therapeutic doses; tolerance to their effect may develop. The range between their hypotensive and undesirable effects may be extremely narrow.

Hydralazine hydrochloride (apresoline) is a slow-acting hypotensor. It rarely reduces blood pressure to normal but, more commonly, to values approaching normal. It is usually used in combination with one of the other drugs. Initially, 25 mg. is given orally four times daily, with gradual increments of 25 mg. until 200 mg. is given four times daily or until reactions occur. The blood pressure of some patients is satisfactorily reduced with smaller doses. Some persons can tolerate the side reactions of apresoline. In others, reactions may be controlled by use of acetylsalicylic acid, tripelennamine hydrochloride (pyribenzamine) or phenobarbital with each dose. Side effects from apresoline are common. The immediate ones are headache, tachycardia, dyspnea, paresthesia, nervousness, dry mouth and depression. Some reactions disappear with continued administration of the drug or reduction of dose. Later side effects (weeks to months) are chills and fever, swelling of the legs, arthritis similar to rheumatoid arthritis and a syndrome simulating acute lupus erythema-

IS IMMUNITY TO TRICHINOSIS BEING NATURALLY ACQUIRED?

JOHN H. THOMPSON, JR., Ph.D.
Rochester, Minnesota

In spite of the fact that trichinosis has been recognized for centuries, its practical control and the ability to diagnose the disease and to treat it successfully remain about as unsolved as they were a century or more ago. Both hogs and man continue to acquire the disease and no specific or nonspecific treatment appears to affect its course. The protean nature of the symptomatology of trichinosis and the ease with which it may be confused with numerous other conditions are well known. No less confusing is the problem of diagnosis from the clinical or laboratory standpoint.

Diagnosis

Numerous immunologic tests done at various stages of the infection apparently have contributed little toward early confirmation of a clinical diagnosis. In addition to the laborious techniques involved in preparing satisfactory materials for immunologic procedures, there are the ever-present questions of interpretation of results. Little question exists that opinions differ on such interpretations or that results of such procedures frequently are misleading. Even the classic eosinophilia so often referred to in the literature as a cardinal diagnostic feature may be lacking or may be a manifestation of other parasitic infections or of nonparasitic disease.

The possibility of direct microscopic demonstration of *Trichinella spiralis* by means of biopsy examination of muscle from the person suspected to have trichinosis has much to offer in the confirmation of a clinical diagnosis. Furthermore, a combination of examination of pressed tissue and digestion of this tissue performed on suspect meat eaten by the patient may provide the earliest and most valuable information available to the clinician. These procedures can be done quickly and require little laboratory equipment.

Examination of pressed tissue is done best by use of heavy glass plates mounted in metal frames that can be squeezed together by means of clamps or a bolting device so that the muscle being examined between the plates is pressed out to reveal its fiber structure clearly under observation at a magnification of 100 times. Many such devices have been described and illustrated in standard laboratory texts.

The material for biopsy should be taken from the pectoralis major muscle at the anterior fold of the axilla. This muscle is selected because it is the most readily available one having the greatest chance of being invaded. The diaphragm and the muscles of the thorax are involved most frequently. Such material should be examined in its entirety and the results must not be regarded as negative without careful scrutiny of all portions. If large pieces of muscle are available, digestion should be carried out after direct microscopic study of the material to reveal any organisms that may have been missed because of their position in the muscle. The sediment in the centrifuged digestion tube then can be examined microscopically for the typically motile larvae of *T. spiralis.* The materials for preparation of the digestive fluid and the apparatus used in this procedure are delineated in the technical appendices of most laboratory manuals.

While it is true that in 1956, as in former years, little other than supportive treatment is available for the person who has trichinosis, early diagnosis is important. There is always the possibility of reducing the degree of infection by purgation of such patients, provided one is equipped to examine material brought to the laboratory. The life cycle of the parasite of trichinosis is such that a

This is the thirty-sixth in a series of editorial reports sponsored by the Minnesota Society of Clinical Pathologists and designed to foster closer relationships between clinicians and pathologists.

period of several days occurs during which intensive purgation can be of value in dislodging worms that ultimately would produce thousands of migrating larvae. The invasion of the tissues by such larvae produces the symptoms of the later stages of the disease. If these larvae are present in sufficient numbers, the infestation can be fatal. Unfortunately, it is true that most of the adult organisms in the intestine have disappeared when larvae are present in the muscles, but adult forms often persist in experimental animals for a long period and continue to give birth to larvae. This probably also is true in human disease.

Immunologic Aspects

It is all too apparent, however, that the message of public-health officials and others has not been taken from the lecture room to the dining room. While it is true that the mortality rate in this country is less now than that recorded in former times, evidence from various samplings of our population demonstrates an incidence of infection of 10 to 20 per cent. Moreover, occasional outbreaks of the disease still appear in which several persons die and numerous others are critically ill. Almost without exception these instances are referable to ignorance of or disregard for the basic facts concerning the proper handling of pork and pork products. A few moments spent occasionally by the family physician to explain to his patients the reason why Moses formulated his code of sanitation possibly might accomplish more than does the shotgun type of attack waged by the public-health official.

Needless to say, the persistence of infection with *T. spiralis* in both humans and hogs after years of effort to reduce it below the current incidence is cause for concern. However, one must not lose sight of the fact that most figures given for incidence are referable to zoologic infections, the figures being derived from post-mortem examination of persons who apparently had no history of clinical trichinosis. Moreover, extensive literature exists on experimental immunity to lethal doses of the larvae induced in animals by means of light zoologic infections. There is only slight reason to doubt that this same protective process is present in the human population, because little else can account for the relatively large incidence of infections revealed by post-mortem examination as compared to the small number of cases diagnosed clinically as trichinosis. Thus, the suggestion has been made that there is actual benefit in the persistence of the infections still found in man and hogs.

The actual proof of reinfection of man by a second exposure to Trichinella larvae subsequent to a light zoologic infection has not been demonstrated. Nothing has been reported in the literature to prove that man does not acquire the same type of protective immunity found in experimentally infected animals. Indeed, there is much evidence that he does. The development of serologic immune reactions in man after infection strongly points to such a result. The lack of clear evidence at necropsy of the existence of both early and late infections in the same person, when so many zoologic infections have been observed, strongly suggests the development of an absolute immunity.

Keeping in mind the possible role of acquired immunity to lethal doses of Trichinella in the general public, one must recall the question raised thirty years ago with reference to the careful evaluation of the more recent proposal to irradiate pork for human consumption. Such a process doubtlessly renders pork free of infective Trichinella, at least in the sense that encysted larvae exposed to such irradiation are sterilized and incapable of reproduction. However, evidence exists that ingestion of such irradiated larvae does not produce immunity to subsequent doses of small numbers of larvae. Animals fed irradiated larvae have been found to be as susceptible as control animals when they are fed challenging doses of normal, nonirradiated larvae.

These experiments suggest that use of such irradiation might result in gradual loss of the protective aspects of the present incidence of zoologic infections. This, together with the sobering fact that there is still no specific treatment for the disease, could result in an increase in clinical trichinosis in both man and hogs, with consequent morbidity and mortality rates comparable to those in earlier records.

When one tampers with natural processes, he may sow a wind and reap a whirlwind.

WHAT ABOUT READING?

In any professional field one of the greatest challenges faced by the worker is keeping abreast of current developments. Medicine, as one of the swiftest moving of the modern professions, presents an almost overwhelming problem in this regard. Yet many doctors handicap themselves unnecessarily in this struggle to keep up with the swiftly flowing currents of their profession. This handicap results from their failure to exploit the potential which they certainly possess for more effective reading.

No doctor needs to be reminded of the constant flow of reading material across his desk. Correspondence, reports, research papers, newsletters, and professional journals constantly accumulate in his basket and his briefcase. That which *must* be read somehow gets read; much that *should* be read does not.

No figures are available on the amount of time spent by medical doctors in reading each day, but it probably corresponds pretty well with the figures derived from studies of the business and industrial executive group. These studies show that the typical executive spends from two to four hours of each work day in doing his necessary reading.

In addition to this mass of work-type reading, consider the amount of general material which could also contribute to personal and professional development. *Publisher's Weekly* reports that in 1955 alone our presses ground out 12,000 different titles. *Ayer's Directory* lists about 2,000 daily and 10,000 weekly newspapers as well as 1,600 weekly and 4,200 monthly magazines.

No sane person would suggest that anyone could (or should) read any great proportion of this bulk. However, it is obviously desirable to do more of it than current studies show is being done.

Naturally, the physician reads more and reads better than a cross-section of the general population. But this is as it should be. Background, experience, and intelligence all tend to favor the professional man as a reader. The disconcerting fact is that this superiority is not nearly as great as it should be. Even given attributes which tend to provide an ideal climate for effective reading, he surpasses the typical adult by only a minor degree in the rate and comprehension of reading.

Recent experience and research have demonstrated time and again that average readers can become superior readers and that superior readers can further extend the margin of their superiority.

Such gains may be achieved through the use of a great variety of aids currently available. The biggest drawback to this individual approach is that it often lacks the regularity and discipline leges and universities offer courses of training in needed to effect the desired changes. Many col- reading efficiency at the extension level. Most have consistently achieved desirable results in the needed directions.

The accelerating rate of advance in the field of medicine will no doubt make it mandatory for more and more doctors to take advantage of this type of assistance.

University of Minnesota

SYPHILOLOGY

Recent years have seen medicine develop into sometimes broad and sometimes narrow fields of specialization. As each new specialty establishes its certifying board, the event is heralded by both warmth and coolness. Medical progress is hailed on one hand and the trend to "super-specialize" decried on the other. Events of recent years may be foretelling the possible disappearance of a once busy specialty—that of syphilology. Three journals once devoted a major portion of their pages to this field. Two *(The Journal of Venereal Disease Information* and *The Journal of Syphilis, Gonorrhea and Venereal Disease)* of these have been discontinued and one *(The Archives of Dermatology and Syphilology)* has abandoned the latter half of its title. The Academy of Dermatology and Syphilology was renamed in December, 1954. In June, 1955, the section of the AMA devoted to diseases of the skin and syphilis likewise was reconstituted since, according to a resolution passed by the House of Delegates . . . "the incidence of syphilis is decreasing and the need for specialized care by dermatologists in the treatment of patients with syphilis is decreasing."

These events are noteworthy and demonstrate the effectiveness of the various public health measures instituted to control venereal diseases. Penicillin has also contributed in a large measure to these changes. Despite these changes, syphilis has by no means been entirely eliminated. The number of persons under treatment for syphilis in the United States in 1954 was 1,921,000, and of these, 86,500 were new cases. Of the new cases, 7,688 were infectious and 7,234 were congenital. Furthermore, in forty-three of the forty-eight states, there has been a steadily increasing incidence of new cases in recent years. Although we have the advantage of more stable peacetime population groups and an effective therapeutic agent, other factors counter-effect these. Large numbers of our youths are still in uniform; interstate and intercontinental travel steadily increases. All of these call for more vigorous employment of time-proven public health measures. Unfortunately, in 1953 there was a sharp curtailment in federal funds for these activities. This has placed the responsibility for these measures in the hands of the state, the community and the individual physician.

The physician, as always, is either the strongest or the weakest link in the chain. Before the advent of penicillin, the hazards of arsenical therapy and the prolonged treatment schedules forced many patients into either public health clinics or a syphilologist's office. In these situations, the case-finding and case-holding efforts were managed by organizations and individuals devoted to these functions. Penicillin, conspicuously with less risk and administered easily over a shorter period of time, is correctly administered by the family physician in his office. Unfortunately, with the conclusion of the injection schedule, the patient is dismissed. This despite the known failure rate of 10 per cent in early syphilis treated with penicillin. Furthermore, little effort is expended in determining the initial source of infection. Contact investigation is not employed. Cases of known treated infections are not reported to the public health authorities of our communities. Case finding and case holding remain the more important responsibilities of the individual physician who assumes the responsibility of treating syphilis.

Robert F. Tilley, M.D.

DOES THE PHYSICIAN NEED AN ARCHITECT?

Yes, no matter what building project interests the doctor, he needs professional planning service that only the architect can provide. In the construction of large hospitals, there is always an architect responsible for the design and construction. This is not always so, for many projects such as small clinics and residential work.

Why is this so? Perhaps an understanding of what the architect does will help. For instance, many people think the architect obtains work by bidding. To the contrary, he is engaged by direct selection or comparative selection by the client on a standard fee basis. Then contractors bid on drawings produced by the architect. By definition an architect is a master builder who professionally plans buildings and supervises their construction. To the durability, adequacy and convenience of a building, he adds that intangible ingredient—good design.

So, then, the physician and the architect are specialists in their respective fields. The contractor-builder is a very necessary part of the team—but not as a designer. Analogous to the nursing profession—certainly a member of the team, but not as a diagnostician or surgeon. The architect like the physician is prohibited from advertising by a code of ethics. The architectural graduate, too, requires his "internship" working in an architect's office several years before being permitted to take his registration examination. And like the medical profession, the architect also has his professional society, the American Institute of Architects.

Any physician would be hesitant to recommend a mid-wife when an obstetrician is readily available. Just as every patient is an individual case, so every building project is a special solution, and today the values of good architecture designed by architects are all around us.

Today, the architect is pioneering in a profession dedicated to better living. He has come to a clear conclusion: for an architectural form to have really lasting appeal it should—above all—make the fullest and best natural use of its materials. His work in designing airports, terminals, hospitals, shopping centers and similar types of modern building reflects today's dynamic architecture as it deals with the movement of people, flow of traffic, requirements of a generation on-the-go.

The architect, through a job well done, every day shows clients and others the saving graces of a well-designed, practical building—and to be practical means to serve in every respect, every direction. He is shouldering a full moral responsibility for building new cities measured to progress.

Robert E. Howe, A.I.A.
Architect

PRESENT STATUS OF VETERINARY MEDICINE

Ever since animals were first domesticated in the pre-dawn of civilization, men associated with them have tried to cure their ills and relieve their suffering. Like the barber shop which was traditionally the birthplace of surgery as applied to man, the first beginnings of veterinary surgery and medicine by persons making a specialty of those activities probably occurred in the blacksmith shop across the street. Doubtless, approximately the same knowledge, skill and sanitation were applied in both establishments.

The real beginnings of modern veterinary medicine, however, were brought about through military necessity. Disastrous immobilization of armies due to sickness and disability of transport animals, resulted in the establishment of schools of veterinary medicine and research into causes and treatment of diseases of animals.

From this meager beginning, veterinary medicine has grown to its present status among the learned professions. Changing economic conditions resulting in greatly increased concentration, transportation and value of domestic animals, has made control of disease a prime necessity. Veterinarians have met this challenge and have made it possible to produce animal products so vital to our economy, on a scale undreamed of half a century ago.

The realization, years ago, that many diseases of domestic animals are transmissible to man, has increased the responsibility of the veterinarian in his relations with other branches of medicine. This challenge has also been met by the profession. Especially trained veterinarians now have their place in most public health organizations. But more important is the responsibility assumed by most practicing veterinarians to promptly report and to participate in the control of dangerous diseases transmissible to man.

Today, a degree in veterinary medicine requires six years of university training, comparable in all respects to that required for graduation in other branches of medicine. The veterinary profession maintains ethical standards on a par with medicine, and veterinarians suffer in no respect when comparing their basic knowledge and technical ability with men in other medical fields. Moreover, they realize that vast fields of medical knowledge yet remain untapped and that maintenance of their present standards requires continued growth, with the same humility and devotion to duty which has marked their progress in the past.

Membership in the veterinary profession of today is a position of trust which any man may well be proud to assume.

HOMEMAKER SERVICE

The Family Service homemaker service is planned to keep children in their own homes when the mother is out of the home temporarily for physical or mental illness. The Service maintains a staff of fifteen women who go into homes for several weeks to take care of the children during the mother's illness. Family Service pays these women by the hour.

The family receiving homemaker service pays the agency. They may pay full cost or part, depending on the income and size of the family. This is a costly child-care plan and is given only when there are two or more children in the home.

The father must make application for this service and a financial plan must be worked out before the homemaker is placed. A written recommendation is required from the physician, which gives some indication of the type of illness and an estimate of the length of time the homemaker will be needed. If the illness is of long duration such as tuberculosis, heart cases and the like, a homemaker is placed for a short time. During this time, the caseworker helps the father make plans for long-time care of the children.

If there are several very young children or an infant, it may be necessary to place the children in boarding homes instead of using homemaker service. Most of the homemakers can work only eight hours a day. The care of young children

---

Seventh editorial in a series on Family Service of Saint Paul, a Community Chest agency.

at night places too great a burden on the father.

The money available from the Community Chest for this service is limited. The refunds from families in 1954 was approximately 13 per cent. The hourly wage paid to the homemaker varies from $1.05 to $1.15, depending on the number of children in the family. There are additional costs such as transportation, insurance and social security for the homemaker.

This program was developed to help families at a point of crisis to keep children in their own homes. If the illness is of long duration, the Service keeps the family together until the father can make arrangements for long-time care.

Homemaker service, like all others offered by Family Service, is available to families living in the Community Chest area which is Ramsey County and West Saint Paul.

(Mrs.) Lois Hoffman
Director of Case Work Services

THE CHANGING PATTERN OF BANK LOANS

The pattern of banking in recent years has been essentially one of change. Especially in the field of loans have changes been made to keep pace with people's needs.

The development of personal credit, primarily to finance the purchase or improvement of homes, purchase of autos and home furnishings, has been typical. Twenty-five years ago, such loans were rare items on a bank's ledger, and installment loans to individuals were almost unheard of. Today, by contrast, more than one-half of the total dollar amount of loans in our bank are made to individuals as opposed to business firms. Two-thirds of these are on a monthly installment basis. The reasons for these changes are simple. They suit the customer's needs, and they are good business for us.

A similar condition prevails in the area of business loans. The types of customers and loans both have changed in these years. New industries like natural gas pipe lines, electronics manufacturers, and chemical companies have replaced others. Long-term credit is common now, whereas "90-day notes" were the unalterable lending device of yesterday. Many loans are made today which look to the projected cash earning power of a business for repayment rather than simply the seasonal liquidation of its inventory or accounts receivable.

Of the many types of loans which a modern bank is eager to make to individuals, the following, though not an exhaustive list, might be of particular interest to professional people:

1. *Real Estate Loans*—made to finance the purchase, construction, or improvement of homes and commercial property. These can be made either on a conventional mortgage basis or with the additional insurance and guarantees of FHA and VA.

2. *Monthly Payment Budget Loans*—used for the purpose of purchasing automobiles, home appliances, or for any other reasonable personal need. Budget loans are frequently made on the borrower's signature only.

3. *Equipment Purchase Loans*—Doctors establishing their practice or extending their equipment facilities frequently find it convenient to finance such purchases, by monthly installments, over an extended period, such as three years.

4. *Single Payment Loans*—loans of this type are frequently made when the customer anticipates being able to repay the advance at one time. They are used for meeting tax payment deadlines, temporary financing to facilitate changing residence, or handling any other unusually heavy expenses. These loans are often secured solely by the customer's signature, but in some cases the bank may ask for the pledge of additional collateral. This may be in the form of almost any readily negotiable personal property. Incidentally, the borrower can usually command a more favorable rate of interest when he supports his loan with a collateral pledge.

These are examples of the changes in bank loaning services referred to at the outset. Perhaps the chief characteristic of modern bank loaning policy is "flexibility." In summary, almost everybody's reasonable borrowing requirements can be attended to quickly and satisfactorily in "today's banks."

The First National Bank of Saint Paul

ALCOHOLISM

The alcoholic isn't just the "bum in the gutter," but he may be John, Mary, Joe—my friend, relative, attorney, accountant, housewife, laborer, every known type of person and of every profession.

Rehabilitation and prevention are costly, but neglect is even more so. Neglect of attention to such a devastating illness runs into the billions of dollars in lost work time, lowered production, loss of trained personnel, waste of public funds in taxes that go for relief, state hospitals, clinics, emergency wards, missions and lodgings, courts and jails, and public welfare services. The appalling waste in human lives, broken homes, and abandoned children is beyond calculation.

The most important recent advance in treatment of alcoholism has not been the discovery of any new cure or wonder drug, but the spread of a more enlightened attitude toward the problem among both the medical profession and the general public.

The Citizen's Commission on Alcoholism of Minnesota, through its offices at 600 Lumber Exchange Building in Minneapolis and its seventy counseling centers throughout the state, carries on an extensive campaign of education by all media at its command to erase the stigma of alcoholism; to make known to professional people as well as to the general public the unbiased, scientific facts about alcohol and alcoholism; to stimulate the establishment of more treatment facilities; to encourage physicians and hospitals to accept alcoholics for treatment; to provide schools and colleges with material to use in their educational programs.

This type of campaign of education acts as a preventive measure by increasing the awareness to the symptoms of alcoholism and thus helps those afflicted to seek treatment in the early stages of the illness.

Paul S. Rahneff, *Executive Secretary*
Citizens' Commission on Alcoholism,
of Minnesota, Inc.

In Memoriam

WILLIAM FRANK MAERTZ

Dr. William F. Maertz, former New Prague physician and civic leader, died January 3, 1956, at the age of seventy. At the time of his death, Dr. Maertz was a member of the staff at St. Peter State Hospital.

Born in New Prague, Dr. Maertz attended schools there and St. John's University; in 1908 he graduated from the medical school of the University of Minnesota. He interned at Minneapolis General Hospital and in 1909 started his practice in New Prague. He remained there until 1945, except for a period of service as a captain in the Medical Corps during World War I and a few years practicing medicine in Lidgerwood, N. D. While in the army, he was battalion surgeon for the 20th Engineers in France.

Dr. Maertz served as president of the Scott-Carver County Medical Society and was a member of the Minnesota State Medical Association and the American Medical Association. He was a member of Alpha Kappa Kappa fraternity.

He was a charter member of the Charles Borak Post No. 45 of the American Legion and served as first post commander. He was a delegate to the first national convention and in 1929 was Commander of the Third District.

Dr. Maertz was mayor of New Prague from 1920 until 1922 and held many offices in civic organizations, including the Community Club, the Catholic Workman, and Knights of Columbus.

He is survived by his wife; three daughters, Mrs. C. L. Cain of St. Paul, Mary Ruth of St. Peter, and Mrs. Robert Turner of Alexandria; his brother, Dr. B. L. Maertz of Willmar; and his sister, Mrs. John J. Kovarik, of Buffalo, New York. His son, Dr. Richard Maertz, preceded him in death.

ACCIDENTAL GUNSHOT WOUNDS

(Continued from Page 160)

of the arterial injury is indicated as soon as the shock phase has been corrected. Nerve injuries of the extremities should not be attacked as a primary problem but should be permitted to be repaired electively within a period of two weeks.

Prevention

A primary consideration in gunshot wounds is their prevention. Physicians in each community have the opportunity to emphasize and reemphasize to their fellow citizens the necessity of careful care in the handling of firearms. Through the cooperation of sportmen's clubs and civic organizations, the physician can bring to the attention of his community the morbidity and mortality associated with gunshot accidents. Simultaneously, he may stress the principles of first aid as applied to such injuries when they do occur.

President's Letter

SURVEY ON NATION'S PHYSICIANS

No doubt you have all been reading the results of the recently published survey on what the public thinks of the nation's physicians. It should be emphasized that although the AMA approved the questionnaire, the public, individual doctors, and the research agency really established the issues.

Interviewees were selected so that the proportion of people from various age, economic, geographical, and other groups matched the proportion of such people in the whole population; questions about general public attitudes were asked only of private individuals.

Some interesting major findings were revealed. One is that most Americans, 82 per cent, have a family physician. And they have a much higher opinion of their own physicians than of the medical profession as a whole.

Only 19 per cent said it was hard to reach their own doctors in an emergency, but 51 per cent thought it was true of doctors generally. Only five per cent said their own doctors were too quick to recommend an operation, but 31 per cent thought it was true of the profession as a whole.

What people like about their doctors and expect from them, it appears, is sympathy, patience, and understanding: not guaranteed cures and "wonder drugs." Eighty-seven per cent thought their own doctors take sufficient personal interest in their patients but, again, only 54 per cent thought this true of the profession in general.

Among those interviewed 43 per cent thought most doctors charge too much, but only 16 per cent thought this was true of their own physicians. About 30 per cent believed "most doctors plan to get rich quick," but only 10 per cent thought this was true of their own doctors.

The basic purpose of this survey was to find out what might be needed to improve doctors' services. If it is to have a value beyond that of the ordinary statistical gimmick, each one of us must act as judge to see if any of the criticisms made in this survey of doctors in general can be applied to ourselves. The whole undertaking will have been futile if the results are not heeded and, certainly, the best guarantee for continuing our tradition of free enterprise in medicine will be to satisfy medical needs as fully as possible.

In closing, let me say that we can be justifiably pleased by the praise many interviewees had for our profession. Apparently most adverse criticism of the medical profession is directed at some other person's doctor.

IOWA DECISION UPHOLDS DOCTORS

The Iowa court case between physicians and hospitals set forth this law: Hospitals cannot hire physicians and bill for their services, thereby engaging in the corporate practice of medicine.

To follow the salient features of the decision, first examine some of the factual conclusions of Judge C. Edwin Moore, who presided over the trial. Judge Moore said:

"The Court finds that pathology and radiology are recognized specialties in the practice of medicine."

* * *

"The Court further finds that laboratory medicine and radiology in their several branches are indispensable to attending physicians in modern medical care, and that facilities must be available in or near hospitals, and that the ownership and maintenance of laboratory facilities is an integral part of a modern hospital."

* * *

"The Court further finds that diagnostic x-ray and radioactive isotope procedures often provide the final diagnosis of the patient's ailment and that fluoroscopy undertaken by the radiologist has the same result, and that the written radiological diagnosis will usually be adopted by the attending physician as the final diagnosis in the case."

* * *

"The pathological and radiological diagnoses are available for acceptance by the attending physician just as are the diagnoses of other consultants in other medical specialties. In many instances, they are so accepted and become the final diagnosis in the case."

* * *

"The Court further finds the great weight of the opinion testimony offered herein establishes that the pathologists and radiologists are engaged in the practice of medicine in their activities as shown by the evidence."

Practice of Medicine Defined

One of the crucial points in the argument was a contention by counsel for the Hospital Association that pathologists and radiologists are not truly in the practice of medicine. Judge Moore cited two sections of the Iowa Code to refute the argument:

"PERSONS ENGAGED IN PRACTICE: For the purpose of this title the following classes of persons shall be deemed to be engaged in the practice of medicine and surgery:

"1. Persons who publicly profess to be physicians or surgeons or who publicly profess to assume the duties incident to the practice of medicine or surgery.

"2. Persons who prescribe, or prescribe and furnish medicine for human ailments or treat the same by surgery.

"3. Persons who act as representatives of any person in doing any of the things mentioned in this section."

"It is not confined to the administering of drugs. Under this statute, one who publicly professes to be a physician and induces others to seek his aid as such is practicing medicine. Nor is it requisite that he shall profess in terms to be a physician. It is enough, under the statute, if he publicly profess to assume the duties incident to the practice of medicine. What are 'duties incident to the practice of medicine?' Manifestly, the first duty of a physician to his patient is to diagnose his ailment. Manifestly, also, a duty follows to prescribe the proper treatment therefor. If, therefore, one publicly profess to be able to diagnose human ailments, and to prescribe proper treatment therefor, then he is engaged in the practice of medicine."

The Judge held that corporations cannot practice medicine, because they are not "persons" in the strictest sense. He pointed to this language used by the Iowa Supreme Court:

"The right to lawfully practice medicine in this state is a personal one. To attain such right, certain statutory requirements must be complied with."

"Medical practice acts are enacted for the protection of the public against the unskilled treatment of the sick or diseased by persons having neither the preparation nor the skill to diagnose diseases or to administer powerful and poisonous drugs. The welfare of the public is of the utmost concern in the enforcement of laws designed to guard and protect the public health. The merits of the secret formulas used in the treatment of cancer and other diseases is not of controlling importance in the decision of this case. Our concern is with the statute, which should be strictly observed."

Same Rules for Non-Profit Hospitals

The decision was reached solely on the basis of the law, and Judge Moore included this statement in his summation:

"The Court casts no reflections at plaintiff hospitals, but good motives do not provide immunity from the application of the statutes or the principles of law. The law applies to all and must not be violated even if the intention is only to do good."

He also said that most of the reasons given in the decisions condemning corporate practice generally are applicable to non-profit corporations.

Judge Moore also gave his opinion that the pathologist or radiologist, by permitting a hospital to bill for medical services in the name of the hospital without the consent of the patient or his legal representative, had violated the provisions of the Iowa Code dealing with "unprofessional conduct" and the division of fees.

Final Conclusions of the Court

The final Conclusions of Law were stated in this way:

> "It is the conclusion of the Court that under the facts established in this case and the law as the Court understands it, that the work done by the pathologist, radiologist, and the technicians working in the pathology and x-ray laboratories, constitutes the practice of medicine.
>
> "That under the Iowa law the privilege of practicing medicine is a personal one requiring qualifications which cannot be met by a corporation.
>
> "That the provisions of Chapter 135B (Iowa Code) do not grant hospitals any right to practice medicine by the operation of pathology and x-ray laboratories in the manner shown by the evidence.
>
> "That plaintiff hospitals are not excluded from the requirements of the Iowa practice acts in regard to the practice of medicine on the basis that they are non-profit corporations or because of long standing custom and inactivity on the part of those charged with enforcing the law, or because of public policy in the absence of legislative enactment.
>
> "The Court does not intend that any findings or conclusions herein affect in any way the obligation of public hospitals . . . to provide medical treatment for indigent persons or tuberculous patients . . . wherein medical treatment is to be provided by hospitals of that category to patients of certain entitlement, nor as to the operation by the State of mental or other hospitals authorized by law.
>
> "The Court is not to be understood as holding the plaintiff hospitals cannot own and maintain facilities of pathology and x-ray laboratories and receive just compensation for the use thereof, as certainly these are essential and necessary parts of a modern hospital, nor that the operation of said laboratories within the law need affect the care and treatment to be given the patients.
>
> "It is the opinion of the Court that the furnishing of proper pathology and x-ray services to the patients in the hospitals can be worked out on the local level and within the law."

COLORADO AND IDAHO DECISIONS

That corporate practice of medicine is illegal was reaffirmed in two other states recently.

In Colorado, a suit by a chiropractic corporation was dismissed when the Judge held that the chiropractic corporation itself was illegal through its corporate "practice of medicine;" and therefore it had no redress in the courts.

This decision held that a state has the constitutional power to prohibit a corporation from practicing a learned profession. Regarding the question of whether a corporation can nonetheless still engage in the practice of a learned profession through its agents and employees who are themselves licensed to practice, the Colorado Supreme Court was quoted as clearly saying that a corporation cannot practice dentistry and that a corporate hospital cannot practice medicine or surgery.

The decision read:

> "If the reason for the rule that a corporation cannot practice medicine is an expressed legislative desire to protect the public against unauthorized, unqualified and improper practice of the healing arts, and to maintain the personalized relationship between the healer and the patient, then whether a corporation was organized for profit or non-profit would be of no legal significance.
>
> "In a hospital the medical services of the interns and residents are only a small part of the total medical services rendered therein, most of the medical services being rendered by individual licensed practitioners who have placed their own patients in the hospital."

It was held that for a corporation to completely staff a hospital and through this staff to treat patients of the corporation was entirely different from usual hospital practice.

In Idaho, the Attorney General gave an opinion on the legality of a sample contract between a hospital and an anesthesiologist.

The contract was basically a percentage agreement between the doctor and the hospital corporation. The issue was whether the contract placed the hospital corporation in the practice of medicine because the physician-anesthesiologist was an "employee."

The Attorney General ruled that it did and advised that hospitals who employed physicians were engaged in the practice of medicine in violation of Idaho law. Also, that the actions of the doctor and the manner in which he would practice his profession could actually be controlled by the hospital under such conditions.

PRESIDENT'S 1956 HEALTH MESSAGE

The President's 1956 health message contained no real surprises. The multi-million dollar program, called "a partnership in which private and governmental enterprise are joined to advance the public welfare" included a request for an appropriation of $126,525,000 for basic medical research. The major share of the funds would go to medical schools, hospitals and private laboratories for their own research.

Congress was asked to authorize $250,000,000 to be spent in construction of research and teaching facilities for medical, dental and public health schools.

Federal reinsurance schemes have been dropped temporarily. An effort will be made to amend antitrust laws to enable private insurance companies to pool their risks, thus encouraging faster progress in extending coverage to older people, to those living in rural areas, to self-employed persons and in providing for catastrophic illness protection.

The President asked for extension for two years beyond June 30, 1957, of the federal-state program to help build public hospitals and other health facilities, and new authorizations of $19 million to carry this out. He also asked for extension of the water pollution act and an increase in funds to broaden the attack on problems of air pollution.

The administration requested that the act permitting federal gifts of polio vaccine to the states for free distribution to children and pregnant women be continued through June, 1957, with an appropriation of $30 million to complete this program.

Another recommendation was for $53 million for construction and improvements at Veterans Administration hospitals. During the 1957 fiscal year, it is expected that the average daily load of the veterans hospitals will be about 111,500 patients.

F. H. Magney, M.D., Secretary

SAINT PAUL QUACK SENTENCED TO WORKHOUSE FOR ONE YEAR

Re: State of Minnesota vs. Frank H. Gold, alias Dr. Frank Stone

On February 7, 1956, Frank H. Gold, thirty-eight, 129 W. Summit Avenue, Saint Paul, after entering a plea of guilty to a charge of practicing healing without a basic science certificate, was sentenced by the Hon. Arthur A. Stewart, Judge of the District Court of Ramsey County, to a term of one year in the Saint Paul Workhouse. The defendant had been charged in a criminal complaint issued on January 20, 1956, with making an examination of a Saint Paul woman, after representing to her that he was "Dr. Frank Stone," a heart specialist. Gold, who had been working as a salesman for an automobile company in Saint Paul, had in his possession at the time of his arrest a prescription pad which had the name "Frank H. Gould, M.D." printed across the top. In the car that the defendant had been using was found a large black medical bag which contained numerous drugs, salves, and lotions, an atomizer, hypodermic syringe and needle, stethoscope and also some surgical instruments.

Gold has never studied medicine but was employed for several years as an orderly at a hospital in New York City, and also worked in the same capacity for at least three hospitals in Minneapolis and Saint Paul. He has three previous convictions in Hennepin County District Court involving violations of the Basic Science Act. Gold was first arrested on May 18, 1946, by Minneapolis police officers for representing himself as a physician and surgeon. He pleaded guilty on May 21, 1946, and on June 12, 1946, was sentenced to a term of one year in the Minneapolis Workhouse. Because it was Gold's first conviction, the sentence was stayed and the defendant placed on probation. In March, 1948, it was learned that Gold was again practicing healing illegally by representing himself as a doctor of medicine. On March 8, 1948, Gold pleaded guilty to the charge and was sentenced by Judge Levi M. Hall to one year in the Minneapolis Workhouse. The defendant was again arrested on January 14, 1950, and on January 18, 1950, he entered a plea of guilty before the Hon. John A. Weeks, Judge of the District Court, to an information charging him with the crime of practicing healing without a basic science certificate. Judge Weeks sentenced Gold to serve one year in the Minneapolis Workhouse. The basis of the charge was that Gold had been representing himself as "Dr. Frank H. Gould" and that he had requested one of the Minneapolis drug stores to print some prescriptions for him and after receiving the prescriptions wrote several. The prescriptions were questioned by a pharmacist which led to Gold's arrest.

Gold was also convicted in 1951 in Federal District Court in Saint Paul of several violations of the World War II Servicemen's Readjustment Act of 1944 for illegally obtaining certain benefits under the act and also for making false statements in doing so. On September 4, 1951, Gold was sentenced by the Hon. Robert C. Bell, Judge of Federal District Court in Saint Paul, to pay a fine and also to serve a one-year term in prison.

The Dean's Page

EDUCATION FOR GENERAL PRACTICE

The increase in medical specialization over the past quarter century has given rise to concern as to an adequate number of family physicians who, it is agreed, provide the basic foundation of good medical service and are able to care for the vast majority of their patients' medical needs. In fact, it has been feared by some that the specialists on the teaching faculties of medical schools may by their very presence encourage students to specialize rather than enter general practice. Actually, medical faculties are thoroughly cognizant of the importance of the family physician and make conscious efforts to set up their teaching programs for the specific purpose of giving their students the best *general medical education* possible, limiting the teaching of the specialities to what the general physician should know. This much we have known. The question is "What has been the result?" A special comprehensive study recently released by Dr. Frank Dickinson, Director of the AMA's Bureau of Medical Economic Research, presents significant information on this point. What Doctor Dickinson has done has been to analyze the data in the AMA Directory of Physicians by type of practice and school and year of graduation.

For the University of Minnesota, this report shows that of the 2,432 physicians who were graduated between 1930 and 1950, 44 per cent are engaged in general practice, 6 per cent are part-time specialists, 23 per cent are full-time specialists, and 27 per cent are not now in private practice. Some of this latter group are in military service and some in residencies. Of all the physicians in active practice who were graduated from medical schools in the United States between 1930 and 1945, 46 per cent are in general practice. For the University of Minnesota graduates, the corresponding figure is 54 per cent in general practice; for the University of Iowa, 46 per cent; for the University of Kansas, 52 per cent; for the University of Nebraska, 53 per cent; for the University of Colorado, 44 per cent; for the University of Wisconsin, 45 per cent; for the University of Illinois, 49 per cent; for the University of Michigan, 34 per cent, and for Northwestern University, 38 per cent.

It is interesting to note also that the number of Minnesota graduates who entered general practice was 41 per cent for the five-year period, 1930-34; 40 per cent, for 1935-39; 48 per cent, for 1940-44; and 46 per cent for 1945-49.

There are other aspects of Doctor Dickinson's report which merit further study, but the above figures indicate that the University of Minnesota is not doing badly in educating general physicians and that among recent graduates of this medical school there is no trend away from general practice into specialization.

—Harold S. Diehl, *Dean*
University of Minnesota Medical School

Reports and Announcements

MEDICAL MEETINGS

State

Minnesota State Medical Association, annual meeting, Mayo Civic Auditorium, Rochester, May 21-23, 1956.

Minnesota Society of Obstetrics and Gynecology, spring meeting, Radisson Hotel. Minneapolis, April 12-14, in conjunction with meeting of American College of Obstetricians and Gynecologists. Secretary, Dr. Edward A. Banner, Rochester.

Minnesota Surgical Society, spring meeting, Rochester, May 11. Secretary, Dr. Owen G. McDonald, Duluth.

Northwest Pediatric Society, spring meeting, Rochester, May 22, in conjunction with meeting of Minnesota State Medical Association. Secretary, Dr. T. C. Papermaster, Minneapolis.

National

American Association of Blood Banks, ninth annual meeting, Somerset Hotel, Boston, Massachusetts, September 3-5. Secretary, Marjorie Saunders, 725 Doctors Building, 3707 Gaston Ave., Dallas, Texas.

American Cancer Society and National Cancer Institute, Third National Cancer Conference, Sheraton-Cadillac Hotel, Detroit, Michigan, June 4-6. Write National Cancer Conferences Coordinator, American Cancer Society, 521 West 57th Street, New York 19, New York.

American College of Gastroenterology, Southern Region, Louisiana State University School of Medicine, New Orleans, Louisiana, April 8. Secretary, American College of Gastroenterology, 33 West 60th Street, New York 23, New York.

American Goiter Association, Drake Hotel, Chicago, Illinois, May 3-5. Secretary, Dr. John C. McClintock, 149½ Washington Ave., Albany, New York.

American Ophthalmological Society, Hot Springs, Virginia, May 31 to June 2.

Gill Memorial Eye, Ear and Throat Hospital, twenty-ninth annual Spring Congress, Roanoke, Virginia, April 2-7.

Industrial Health Conference, sponsored by organizations of industrial physicians, dentists, nurses, hygienists and government agency workers, at Convention Hall, Philadelphia, Pennsylvania, April 21-27. Write Industrial Health Conference, 28 East Jackson Boulevard, Chicago 4, Illinois.

Medical Library Association, fifty-fifth annual meeting, Hotel Statler, Los Angeles, California, June 18-22. Write Mrs. Ella Crandall, Librarian, Los Angeles County General Hospital, 1200 North State Street, Los Angeles 33, California.

Oregon Academy of Ophthalmology and Otolaryngology, fifteenth annual Spring Convention in Ophthalmology and Otolaryngology, University of Oregon Medical School, Portland, Oregon, March 19-22.

International Meetings

Canadian Medical Association, Quebec, Canada, June 10-14. Secretary, Dr. Arthur D. Kelly, 150 St. George St., Toronto, Ontario, Canada.

Congress of International Anesthesia Research Society, Miami Beach, Florida, April 9-12. Write Dr. R. J. Whitacre, 13951 Terrace Road, Cleveland, Ohio.

Congress of International Society of Hematology, Hotel Somerset, Boston, Massachusetts, August 27 to September 1. Secretary, Dr. W. C. Maloney, 39 Bay State Road, Boston, Massachusetts.

Inter-American Congress of Cardiology, Havana, Cuba, November 4-10. Write Dr. Ramon Aixala, Apartado 2108, Havana, Cuba.

International Academy of Pathology, Cincinnati, Ohio, April 24 and 25. Secretary, Dr. F. K. Mostofi, Armed Forces Institute of Pathology, Washington 25, D. C.

International Academy of Proctology, eighth annual convention, Drake Hotel, Chicago, Illinois, April 23-26. Secretary, Dr. Alfred J. Cantor, International Academy of Proctology, 147-41 Sanford Avenue, Flushing 55, New York.

International Congress of Clinical Chemistry, Hotel New Yorker, New York, September 9-14. Secretary, John G. Reinhold, 711 Maloney Building, University of Pennsylvania, Philadelphia 4, Pennsylvania.

National Congress of Pediatrics, Cuidad Universitaria, Mexico D. F., Mexico, May 1-5, 1956. Dr. Ignacio A. Cisneros, chairman, Calzada de Madereros No. 240, Mexico 18, D. F., Mexico.

Pan American Medical Association, Tenth Inter-American Congress, Mexico City, Mexico, April 15-21, 1957. Executive director, Dr. Joseph J. Eller, 745 Fifth Avenue, New York, New York.

World Medical Association, Havana, Cuba, October 9-15. Secretary, Dr. Louis H. Bauer, 345 E. 46th St., New York 17, New York.

SCHERING AWARD COMPETITION

The eleventh annual Schering Award competition has been announced. Medical students are invited to select one of three subjects and submit papers in competition for a $500 first prize and a $250 second prize in each of the three subject classifications. Subjects for 1956 are as follows: (1) The Clinical Use of Adrenocortical Steriods in Collagen Diseases, (2) Metabolic Aspects of the Aging Process, and (3) New Applications of Antihistamines in Medicine and Surgery.

Information and entry forms are being distributed in medical schools. Students who wish to participate should submit entry forms before July 1, and manuscripts must be postmarked not later than September 30. The contest is sponsored by Schering Corporation.

WINONA COUNTY SOCIETY

Dr. W. O. Finkelnburg, Winona, was elected president of the Winona County Medical Society at a meeting of the organization at the Hotel Winona on January 9. He succeeds Dr. Philip Heise in the post. Named as vice president of the group was Dr. Sidney O. Hughes, with Dr. L. J. Wilson as secretary and Dr. W. W. Haesly as treasurer, all of Winona.

Dr. Lewis Younger, Fair Oaks, was named delegate to the state association. Dr. H. W. Satterlee, Lewiston, was named alternate.

The meeting was attended by twenty-one Winona County physicians and their wives.

ST. PAUL SOCIETY OF INTERNAL MEDICINE

The St. Paul Society of Internal Medicine will hold a meeting at the St. Paul University Club on April 19, at :30 p.m. Dr. M. E. Janssen will present a paper on "Paroxysmal Hemoglobinuria." Also on the program will be a discussion of the Blue Shield Plans A and B for major medical illness.

ST. PAUL SURGICAL SOCIETY

The next meeting of the St. Paul Surgical Society will be at the Minnesota Club in St. Paul on March 21, with dinner at 6:00 p.m. preceding the scientific meeting. The principal speaker will be Dr. Donald McCain.

AERO MEDICAL ASSOCIATION

The annual meeting of the Aero Medical Association will be held at the Drake Hotel, Chicago, Illinois, on April 16, 17, and 18, 1956.

This year's meeting will provide the most comprehen-ive review of current progress in Aviation Medicine ver presented. There will be 137 papers presented dealing with every aspect of the field and coming from military and civilian sources in nine countries.

Of particular interest will be the section meetings which will include in their agenda panel discussions of ital topics by top authorities in each field. Those sections convening will include the following sub-special-ies: Space Medicine, Civil Aviation Medicine, Avia-ion Physiology, Aviation Ophthalmology, Acceleration nd Deceleration. Air Passenger Transportation, Noise nd Vibration, Pilot Selection and Aviation Psychology, Personal Equipment, Aviation Pathology, Aviation Medical Education, and a combined symposium on Escape from High Performance Aircraft.

All members of the profession are cordially invited to attend any or all of these sessions.

The Wives Wing of the Aero Medical Association, composed of over 300 wives of Association Members, will hold their annual functions on the same dates. All wives of persons in the profession are also cordially invited to attend.

COURSES IN PEDIATRICS

The following short courses will be conducted at The Children's Hospital of Philadelphia in May and June, 1956.

1. Pediatric Advances for Pediatricians and General Practitioners. May 28 through June 1, 1956. A Refresher Course conducted by the Staff of the Children's Hospital of Philadelphia, in collaboration with the Department of Pediatrics of the University of Pennsylvania and the Camden Municipal Hospital. Tuition—$100.00.
2. Practical Pediatric Hematology. June 4, 5, and 6. Conducted by Dr. Irving J. Wolman and other members of the Hematology Department of the Children's Hospital, under the auspices of the Graduate School of Medicine, University of Pennsylvania. Tuition—$60.00.
3. Blood Group Incompatabilities and Erythroblastosis Fetalis. June 7 and 8. Conducted by Dr. Thomas R. Boggs, Jr., of the Philadelphia Serum Exchange of the Children's Hospital of Philadelphia, under the auspices of the Graduate School of Medicine, University of Pennsylvania. Tuition—$50.00.

For information, write to Irving J. Wolman, M.D., Children's Hospital of Philadelphia, 1740 Bainbridge Street, Philadelphia 46, Pennsylvania.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

An examination for medical licensure will be given by the Minnesota State Board of Medical Examiners beginning Tuesday, June 12, 1956, continuing on Wednesday and concluding with a practical examination on Thursday, June 14, 1956. Candidates should have their completed applications, required credentials and fees on file thirty days prior to the examination.

CONTINUATION COURSES AT THE UNIVERSITY OF MINNESOTA

Center for Continuation Study

Dates	*Course*	*Guest Speaker*
March 19-21	Cardiovascular Diseases for General Physicians	Dr. Hans Hecht, University of Utah College of Medicine
April 7	Trauma for General Physicians	
*April 9-11	Endocrinology for General Physicians	Dr. Peter H. Forsham, University of California Medical School
*April 16-18	Radiology for General Physicians	
May 7-12	Electrocardiography for General Physicians	

*Dates changed since previous announcements.

Woman's Auxiliary

MOWER COUNTY AUXILIARY

Mrs. L. J. Leonard

Editor, Minnesota Medicine Auxiliary News

In response to my December request to county presidents for material to be used in MINNESOTA MEDICINE, I received a newspaper clipping from Mrs. Robert R. Wright, Austin, president of the Mower County Auxiliary. It was excellent publicity, consisting of five pictures and a news column covering their fifth annual effort in behalf of nurse recruitment and allied medical careers.

On January 23, the Mower County Auxiliary sponsored a tour of St. Olaf Hospital in Austin for 200 high school girls interested in these professions. The tour was followed by a tea at the local YWCA and several of the girls' mothers also attended.

Miss Miriam Berg and Miss Lois Atheson, instructors at the Methodist Kahler School of Nursing, Rochester, were speakers. They stressed the fact that hospital admissions had doubled since 1935, creating a constantly increasing need for medical personnel. They urged the selection of science courses in high school, with an emphasis on chemistry, as these subjects are important entrance requirements for admission to nurses' training schools. Those who would enjoy the service of nursing and have a good scholastic average should apply.

Other fields discussed were vocational nursing, medical technology, x-ray technology, occupational therapy, physical therapy and dietetics. A film, "When You Choose Nursing," was shown.

Mr. Peter Bye, assistant administrator at the hospital, conducted one of the tours and explained the use of the x-ray machine.

The news picture showed eighteen of the girls who attended, which was outstanding co-operation from the newspapers. A story like this has a great deal of local interest and is good public relations. In charge of arrangements were Mrs. Stanley Peterson, Mrs. E. C. Sargent and Mrs. George Stahl.

Letter to the Editor

Dear Editor:

I know that this is an unusual request, but I should appreciate any help that you can give me in this matter. I am attempting to locate a Miss Virginia McLoad who graduated from Pine Bluff High School in 1931 and who is a graduate nurse married to a doctor now practicing in Minnesota.

Both Virginia and her husband did medical work in Puerto Rico in the late '30s or early '40s. I know this is pretty scant information to go on, but I have exhausted all other sources of information.

Yours very truly,
LESTER SILBERNAGEL

Pine Bluff, Arkansas
January 17, 1956

HYPOTENSIVE DRUGS

(Continued from Page 173)

tosus. Such reactions can be completely reversed by discontinuing use of the drug.

Hexamethonium and pentapyrrolidinium bitartrate (ansolysen) are potent hypotensors and should be used only for severe hypertension. Treatment should be initiated with the patient under observation in the hospital, and the patient must learn to determine his own blood pressure and regulate dosage. The drugs can be given subcutaneously or orally but the oral route has been used with increasing frequency. The dosage varies greatly with each person. Initial oral doses of hexamethonium are 125 to 250 mg. of the salt before each meal and at bedtime; each day individual doses are increased by 125 mg. The maximal dose is 1,250 mg. four times daily. Initial oral doses of ansolysen are 20 mg. given in the same manner as is hexamethonium. Doses are increased by increments of 20 to 40 mg. and the maximal dose is 400 to 500 mg. four times daily.

Untoward side reactions of these ganglion-blocking agents are orthostatic hypotension, blurring of vision, constipation and urinary obstruction, especially in elderly men. A few patients have paralytic ileus, which necessitates discontinuance of therapy. Constipation, which is common, usually can be controlled by mild laxatives and sublingual use of neostigmine, 15 to 30 mg. one or more times a day. Nocturia and difficulty in urination may be relieved by sublingual use of bethanechol chloride (urecholine), 5 mg. one to three times a day. In some instances, transurethral prostatic resection must be performed or treatment with the drug discontinued. Impotence is common.

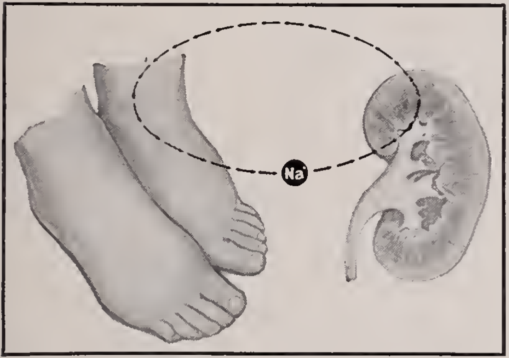
Treatment of essential hypertension by drugs is as yet not completely satisfactory. All available drugs have unpleasant and sometimes serious side effects. However, judicious and intelligent use of one or more of the agents mentioned will reduce blood pressure in most cases of essential hypertension.

The Savings Bonds sales program is truly an "All-American" program. Every participant can take pride in it. The savings—large and small—which have gone into this program have been building important financial reserves for our people which will enable them to enjoy a finer, more secure future. These investments are making a vital contribution to the sound management of our Nation's finances.—GEORGE M. HUMPHREY, Secretary of the Treasury.

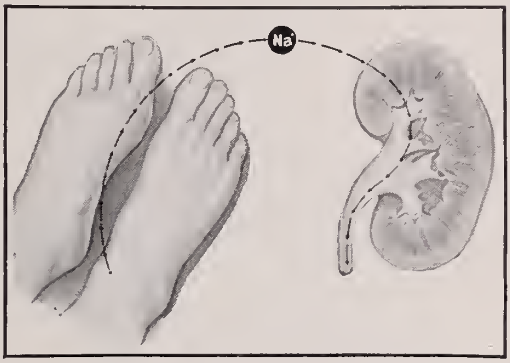
MICTINE* — ORAL NON-MERCURIAL DIURETIC

New Orally Effective Diuretic for Congestive Edema

Best results are obtained when Mictine is administered with meals on an interrupted dosage schedule.



WITHOUT MICTINE — *Prior to diuretic therapy excessive sodium and water are characteristically retained in the edematous patient.*



WITH MICTINE — *Inhibition of the reabsorption of sodium ion leads to an increased excretion of sodium ion, water and chloride.*

An effective diuretic has been described as one which causes excretion of water, sodium and chloride in amounts sufficient to reduce the edema but not to result in salt depletion.

Mictine (brand of aminometradine) introduces to clinical practice an *improved* diuretic which not only meets the standard qualifications but has these seven additional advantages:

Mictine is orally effective; it is not a mercurial; it has no known contraindications; it does not upset the acid-base balance; it exerts no significant influence on electrolyte balance; it may be given in the presence of renal or hepatic diseases; it is well tolerated.

As with most effective therapeutic agents, in high dosage Mictine may cause some side effects in some patients; however, on three tablets daily side effects (anorexia and nausea, rarely vomiting, diarrhea or headache) are minimal or absent.

Clinically, Mictine is useful in the maintenance of an edema-free state in all patients and for initial and continuing diuresis in mild or moderate congestive failure. It is not intended for initial diuresis in severe congestive failure unless either sensitivity or tolerance to other diuretics has developed in the patient.

The maintenance dosage of Mictine, as well as for initial diuresis in mild or moderate congestive heart failure, is one to four 200-mg. tablets daily in divided doses; the dosage for initial diuresis in severe congestive failure, under the conditions already described, is four to six tablets daily. For either use, it is recommended that Mictine be prescribed with meals on interrupted dosage schedules; that is, prescribing Mictine on alternate days or for three consecutive days and omitting it the next four days.

Descriptive literature and clinical trial packages are available on request to . . . **SEARLE** P. O. Box 5110, B
Chicago 80, Illinois

General Interest

Minnesota physicians are invited to submit items of "general interest" concerning themselves or their colleagues to Minnesota Medicine, 2642 University Avenue, St. Paul. Only the facts are needed—who? what? where? when? why?—since items will be rewritten for conformity of style.

* * *

Dr. A. B. Rosenfield, chief of the section of maternal and child health for the Minnesota Department of Health, Minneapolis, has been named to head an advisory committee on accident prevention. He was appointed to the post by the Minnesota Society for Crippled Children and Adults, which conducts an accident prevention program in public schools.

* * *

Dr. John Hult of the Raiter Clinic, Cloquet, has been made a diplomate of the American Board of Pediatrics. Dr. Hult has been practicing at the Raiter Clinic since July, 1954. Previously he was chief resident pediatrician for the University of Colorado Medical Center in Denver.

* * *

New chief-of-staff at St. Barnabas Hospital, Minneapolis, is **Dr. Lloyd F. Sherman,** who succeeds **Dr. Arthur H. Mork** in the post. Dr. Sherman has been a member of the staff since 1950. Other officers elected by the medical staff of the hospital include **Dr. William T. Walsh,** vice chief-of-staff, and **Dr. John T. Moehn,** re-elected secretary-treasurer.

* * *

Dr. Raymond D. Pruitt, Rochester, associate director of the Mayo Foundation, was one of the speakers at the fifty-second annual Congress of Medical Education and Licensure in Chicago on February 11 through 14. The meeting was sponsored by the Council of Medical Education and Hospitals of the American Medical Association.

* * *

Draft board orders for **Dr. John R. B. Fischer,** Blooming Prairie, were cancelled January 15 following a review of the city's medical situation. It was decided that his services were needed by the city, which has only one other physician, **Dr. Benedik Melby.** Previous to the draft call, issued by an out-of-state draft board, Dr. Fischer had been denied a commission in the armed forces due to physical handicaps.

* * *

Dr. Bernard E. O'Reilly has been elected president of the medical staff of St. Joseph's Hospital, St. Paul. Other staff officers elected include **Dr. C. L. Cain,** vice president; **Dr. Richard M. Leick,** treasurer, and **Dr. Hubert F. Flannery,** secretary.

Appointed chiefs of the major services are **Dr. John F. Briggs,** medicine; **Dr. Charles E. Rea,** surgery; **Dr. Joseph W. Goldsmith,** obstetrics-gynecology; **Dr. John E. Teisberg,** general practice, and **Dr. John J. Galligan,** pediatrics.

Dr. Charles W. Mayo, Rochester, has been appointed by President Eisenhower as alternate representative on the executive board of the World Health Organization. Dr. Mayo attended a meeting of the organization as a delegate last spring in Mexico City.

* * *

Principal speaker at a meeting of the Rotary Club in Minneapolis on January 27 was **Dr. Harold S. Diehl,** dean of medical sciences at the University of Minnesota. Dr. Diehl discussed international problems in the field of world health.

* * *

Dr. Malcolm B. Dockerty, Rochester, conducted a symposium on gynecology at a three-day sectional meeting of the American College of Surgeons at Jacksonville, Florida, January 16 through 18.

* * *

Dr. Jack V. Wallinga, formerly an instructor in child psychiatry at the University of Minnesota Medical School, was recently promoted to the rank of lieutenant commander in the Navy Medical Corps. Dr. Wallinga has been on duty with the neuropsychiatric service at Oak Knoll, U. S. Naval Hospital, Oakland, California, since August, 1954. He conducts a psychiatric clinic for disturbed young dependents of naval personnel.

* * *

Lt. Col. Harold G. Benjamin, Minneapolis physician since 1935, has assumed command of the 204th Medical Battalion, Minnesota National Guard. Headquarters of the battalion are in Minneapolis, with units in St. Paul and Zumbrota.

* * *

New chief-of-staff of the Olmsted Community Hospital, Rochester, is **Dr. John E. Verby,** a member of the Olmsted Medical Group in Rochester, who succeeds **Dr. T. O. Wellner** in the post. Other new staff officers of the hospital include **Dr. A. F. Risser,** Stewartville, vice president, and **Dr. E. W. Ellis,** Elgin, secretary-treasurer.

* * *

An emergency tracheotomy, performed at a dinner meeting of the St. Paul Surgical Society on January 25, saved the life of **Dr. Carl J. Fritsche,** New Ulm When he choked on a piece of meat during dinner and collapsed, unable to breathe, he promptly wa placed on the floor by **Dr. Howard A. Vogel** of New Ulm and **Dr. J. E. Schroeppel** of Winthrop. Then Dr **Nathan C. Plimpton,** Minneapolis, performed an emer gency tracheotomy, using a pen-knife. Able to breath again, Dr. Fritsche coughed and dislodged the obstruc tion. He was taken to St. Luke's Hospital for furthe care.

* * *

Dr. Ann W. Arnold has been elected president an chief of the medical staff of Ripley Memorial Hospita (formerly Maternity Hospital), Minneapolis. Other sta

New STEELINE Pediatric Table

Eases the burden of the physician's daily work

Includes built-in tare balance scale, built-in measuring rod, foam rubber cushion and electrical outlets with cord and plug—there are no accessories to buy. Top quality construction features include all-welded steel body, two roomy drawers and a large open compartment with shelf, providing easy, unhampered access to instruments and supplies. Front edge is protected from wear by a stainless steel baffle plate. Despite the fact that this new table has been designed to provide the physician with the best modern equipment, efficient modern production methods in our own factory permit us to keep the price well below that of comparable models. Write today for complete information.

COBAMIN

COBAMIN
10 cc.
INJECTABLE
THE ULMER PHARMACAL COMPANY

The classic neurological symptoms of thiamine deficiency often resembles those of cyanocobalamin (Vitamin B12). Several of these well defined conditions have been treated satisfactorily with either or both of these factors. Adequate doses are necessary to influence prognosis favorably.

COBAMIN combines thiamine (100 mg.) and Vitamin B12 (500 mg.) per each cc. in a stable isotonic solution for intramuscular use. Stubborn neuropathies of the order listed and osteoarthritis frequently are controlled with COBAMIN therapy.

Faculty members of the University of Minnesota Medical School and private practitioners conducted a free public health forum in St. Paul on January 25 and in Minneapolis on January 29, sponsored by the Minnesota Medical Foundation. Panel members answered questions which had been submitted by residents of both cities.

Chairman of the St. Paul forum was **Dr. A. E. Ritt**, president of the Ramsey County Medical Society. Acting as moderator for both meetings was **Dr. Cecil J. Watson**, chief of internal medicine at the University of Minnesota. Members of the panel for the St. Paul meeting were **Dr. Louis Tobian** and **Dr. Richard L. Varco**, faculty members of the University Medical School, and **Dr. John F. Briggs** and **Dr. Joseph F. Borg**, private practitioners.

At the Minneapolis forum **Dr. Robert E. Priest**, president of the Hennepin County Medical Society, served as chairman. The panel members, in addition to Dr. Tobian and Dr. Varco, with Dr. Watson as moderator, were **Dr Reuben A. Johnson** and **Dr. Harold Miller**, both in private practice.

* * *

Dr. C. W. Mayo was re-elected chairman of the Mayo Association at the annual meeting in Rochester on February 3. **Dr. Waltman Walters** and **Dr. Samuel F. Haine** were re-elected as vice chairmen.

* * *

Dr. Lowell L. Henderson, Rochester, was elected t fellowship in the American Academy of Allergy at th annual meeting of the organization in St. Louis, Missouri, on February 7.

* * *

Dr. George C. Hendrickson, member of the medica service staff of the Veterans Administration at For Snelling for ten years, has been appointed to the medica staff of the VA center at Fargo, North Dakota.

Dr. George L. Garske has moved his offices from 32 Doctors Building to 431 Marquette Bank Building, Minneapolis. His practice is limited to urology.

MINNESOTA BLUE CROSS-BLUE SHIELD

Since its origin in 1933 to December 31, 1955, Minnesota Blue Cross has provided 11,512,787.8 days hospital care for 1,897,661 participant subscribers.

Payments in the form of hospital benefits during th period totaled $122,898,837.

During the year 1955, hospital payments totalin $19,320,569.35 provided 1,033,781.2 days of hospit care for 167,667 Minnesotans.

The amount of benefits paid represented an increase of $1,573,463.17 over 1954; the number of days care increased 30,228.9 and the total number of hospital cases increased 1,678 over the same period.

Nearly 1,027,000 Minnesotans were covered by Blue Cross as of December 31, 1955, representing an increase in participation of 26,917 persons during the year.

In keeping with the policy of affording eligible Minnesotans the opportunity to provide themselves and their families the hospitalization protection they need, Blue Cross is announcing the availability of the Optional Series Contracts. These contracts are for non-group participants, that is, individuals do not have to belong to a group.

These are completely flexible contracts enabling eligible applicants to select the room and board coverage that best fits their needs and income.

From Minnesota Blue Shield's beginning in 1947 through December 31, 1955, over $25,282,130 has been paid to doctors for services rendered Minnesota Blue Shield subscribers. Of this impressive total $5,736,166 was paid by Blue Shield for doctors' services rendered subscribers during the year 1955 and $4,970,231 was paid for care of subscribers during 1954. The amount paid in 1955 is $765,935 more than was paid in 1954. This figure represents an increase of more than 15 per cent over the amount paid in 1954. During 1955 Blue Shield provided an average monthly payment of more than $478,013 for care of subscribers.

The Blue Shield statistical data for the year 1955 shows that 200,466 doctors' services were provided Blue Shield payments. In 1954 payment was provided for 169,445 doctors' services rendered subscribers. The number of services for which Blue Shield provided payment in 1955 is 31,021 greater than the number of services paid in 1954.

Blue Shield enrollment as of December 31, 1955, numbered 729,462 participant subscribers. The number of subscribers enrolled in Blue Shield as of December 31, 1955, was 58,705 greater than the number of subscribers enrolled as of December 31, 1954.

Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

VASCULAR SURGERY IN WORLD WAR II. Edited by Daniel C. Elkin, M.D., and Michael E. DeBakey, M.D. 464 pages. Illus. Price $4.25, buckram. Washington 25, D. C.: Superintendent of Documents, U. S. Printing Office, 1955.

THE EXCEPTIONAL CHILD FACES ADULTHOOD. Proceedings of the 1955 Spring Conference of the Child Research Clinic of the Woods Schools, held in New York City, May 6 and 7, 1955. 114 pages. Price $1.00 single copies; 75c each two to nine copies; 65c ten to forty-nine copies; 60c fifty to ninety-nine copies. Langhorne, Pa.: Woods Schools, 1955.

PREVENTIVE MEDICINE IN WORLD WAR II. Vol. III. Personal Health Measures and Immunization. Colonel John Boyd Coates, Jr., M.C., Editor-in-Chief; Ebbe Curtis Hoff, Ph.D., M.D., Editor for Preventive Medicine; Phebe M. Hoff, M.A., Assistant Editor. 394 pages. Illus. Price $3.25, buckram. Washington 25, D. C.: Superintendent of Documents, U. S. Printing Office, 1955.

HIPPOCRATES ON INTERCOURSE AND PREGNANCY. An English translation of "On Semen" and "On the Development of the Child." By Tage U. H. Ellinger, Sc.D., M.A. With an introduction by Alan F. Buttmacher. 128 pages. Price $2.50. New York: Henry Schuman, Inc., 1952.

The amazing fact learned from this work of Hippocrates is that in the fifth century before Christ there was much information known about reproduction, embryology and heredity. Intermixed with the brilliant observations are many strange and delightful ideas that make the reading interesting.

Human dissection was not practiced at the time this work was originally written. Thus the anatomy described is that of lower animals and describes a bicornuate, double uterus instead of one single chambered uterus present in the human.

D.W.K.

THE ONLY NEW MULTIFOCAL DESIGN IN 20 YEARS!

This new PC lens is completely identifiable for your protection*

The segment of the new PC lens has a distinctive shape — straight top with rounded corners — a protection against cheap imitations for you and your patients.

Besides being of highest quality, the PC lens includes these outstanding features:

- Straight top with rounded corners — Fused!
- The Barium crown segment assures freedom from color aberration to the fullest extent possible.
- The top line is slanted downward to make it least noticeable to the wearer, yet maintaining highest cosmetic qualities.
- Rounded corners make all of the segment useful.
- The optical center of the segment is only 4½ mm below the top line to minimize image jump.
- Slab-off prism can be ground coincident with the straight top line of the segment.
- The bifocal segment is available in two sizes — 21 mm wide by 15 mm high or 24 mm wide by 16¾ mm high.
- The trifocal segment is 24 mm wide, 6¾ mm intermediate with an overall height of 17½ mm.

First quality • Complete range of base curves

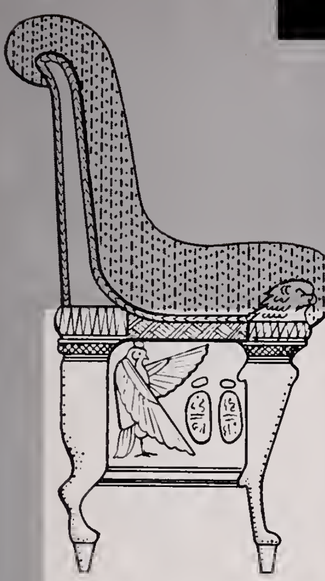
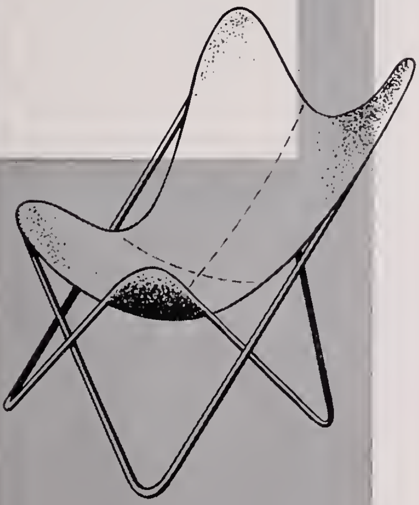
FOR HYPERTENSION



"AN ALLIANCE
OF THE CLASSIC
AND CONTEMPORARY"



Synergistic Therapy with New THEOMINAL® R.S.

Now you can give your hypertension patients
the compound therapeutic advantages
of two successful hypotensive agents:
Theominal (theobromine with Luminal®)
and purified Rauwolfia serpentina alkaloids.

THEOMINAL R. S. *gives Better Control of Cardiovascular and Subjective Symptoms*

Theominal R. S. offers both the vasodilator and myocardial stimulant actions of theobromine with Luminal and the moderate central hypotensive effect of Rauwolfia serpentina. Gentle sedation calms the patient and a feeling of "relaxed well-being" is established. With Theominal R. S. the therapeutic potency of each of the components is enhanced and the chance of a patient's sensitivity to any one drug is lessened.

Each Theominal R. S. tablet contains:

Theobromine	0.32 Gm. (5 grains)
Luminal	10 mg. (⅙ grain)
Purified extract of Rauwolfia serpentina alkaloids	**1.5 mg.**

DOSE: **1 tablet two or three times daily.**

SUPPLIED: **bottles of 100 and 500 tablets.**

Winthrop
LABORATORIES

Lilly

no nicer way to . . . . . .

SUSPENSION
Chloromycetin®
PALMITATE

pleasant-tasting CHLOROMYCETIN for pediatric use

When a youngster's condition calls for CHLOROMYCETIN (chloramphenicol, Parke-Davis) you can make the treatment pleasant by prescribing SUSPENSION CHLOROMYCETIN PALMITATE. Because children like the taste of this custard-flavored suspension, missed doses and spilled doses are avoided. Each teaspoonful is willingly taken…and swallowed.

Precise adjustment of dosage, as directed, is made easier for the child's mother with SUSPENSION CHLOROMYCETIN PALMITATE. The fact that it needs no refrigeration is an added convenience.

CHLOROMYCETIN is a potent therapeutic agent and, because certain blood dyscrasias have been associated with its administration, it should not be used indiscriminately or for minor infections. Furthermore, as with certain other drugs, adequate blood studies should be made when the patient requires prolonged or intermittent therapy.

supplied:
SUSPENSION CHLOROMYCETIN PALMITATE,
containing the equivalent of 125 mg.
of CHLOROMYCETIN per 4 cc.,
is available in 60-cc. vials.

Rochester Welcomes . . .

The Minnesota State Medical Association

for the

103rd Annual Meeting

May 21-23, 1956

Photos courtesy of Mayo Clinic an
Rochester Chamber of Commerce.

Convention City

Rochester, a city rich in history, was settled in the early 1850's by men who recognized its potential as an agricultural center. After the turn of the century, fate made it a world center of medicine. Today it is a bustling city of many pursuits.

Rochester, county seat of Olmsted County, is situated in the heart of southern Minnesota's rich agricultural and dairying section, approximately 75 air miles southeast of Minneapolis and St. Paul.

Rochester was founded in 1854 as a crossroads campground for wagon trains that were pouring into Minnesota. From a population of less than 50 in 1856, it has grown to become a city of 35,000 residents, with a transient population annually of 350,000.

Rochester is a fascinating combination of industry, commerce, fine homes and cultural institutions in the midst of an agricultural region.

Rochester's Health Center, housing the city's health department, gives Rochester residents, and particularly children, excellent care and health protection.

Rochester's beautiful and complete public library carries out the city's theme of service to its citizens, including audio-visual, club, and children's rooms.

...Rochester Welcomes You!

Historical Museum—You are invited to visit the museum of the Olmsted County Historical Society, located downstairs in the public library building at the corner of Second street and Third avenue S.W. Come in and browse around. View the relics of pioneer Olmsted county.

Public Library—Transient visitors are invited to make use of the facilities of the Public Library, situated one block west of the Mayo Clinic building. The reading room provides newspapers, periodicals and transient service, while the Kellogg Room is a comfortable, quiet place for reading amid beautiful surroundings.

Art Center—For a pleasant way to spend your free time, visit the friendly Rochester Art Center at the corner of Third Avenue and West Center (about two blocks from the Clinic). Here you may enjoy an interesting exhibit of paintings, sculpture or crafts. You may visit the studio where classes in drawing, painting and pottery are being held, or the staff will help you in selecting attractive prints for your home from the print collection, at very modest prices.

MASONIC TEMPLE BUILDING

...Rochester Welcomes You!

The Mayo Clinic—The term "Mayo Clinic" usually refers to three buildings in downtown Rochester: the small "red brick" building built in 1914, the twenty-story tower-topped structure built in 1928, and the new ten-story clinic building completed in 1954.

The 1914 building is now used for clinical laboratory work. The 1928 building is largely devoted to therapy and to education through the Mayo Foundation. The new structure, called the New Clinic, is mainly used for diagnosis and patient-physician consultations. All three buildings are connected to each other.

The New Clinic building is 150 feet high and has about 49,000 square feet of working area on each of its ten floors. It is constructed so that up to eight more stories can be added to the present structure if needed. Designed in the form of a Greek cross, it has more than twice the space of the 1928 building.

A fourth Mayo Clinic building, Medical Sciences, is located one block south of the New Clinic. In it are laboratories for medical investigation and research. Special diagnostic procedures for patients are also carried out there.

...Rochester Welcomes You!

Clinic Carillon—The Rochester Carillon, located in the tower of the Mayo Clinic building, is a gift of Drs. William and Charles Mayo. The carillon consists of twenty-three bells having a total weight of 36,988 pounds. The largest bell weighs 7,840 pounds and the smallest 168 pounds.

The bells are proportioned scientifically to produce a flowing evenness of effect throughout the whole compass of the carillon. They are made of the purest bell metal, cast in the foundry of Gillett & Johnston of Croydon, England. Before shipment to Rochester, the bells were played by the foremost Belgian carillonneur and were consecrated by the Archbishop of Canterbury.

The carillon is tuned to the notes of the chromatic scale, upon which music in two or more parts may be played. The bells are hung stationary and are played automatically or by the carillonneur, James J. Drummond. Half-hour recitals are given on Sundays, Wednesdays and Fridays.

Rochester's Lobb Field is one of the finest. Serving three major airlines as well as a heavy flow of private planes, it receives visitors from all over the world.

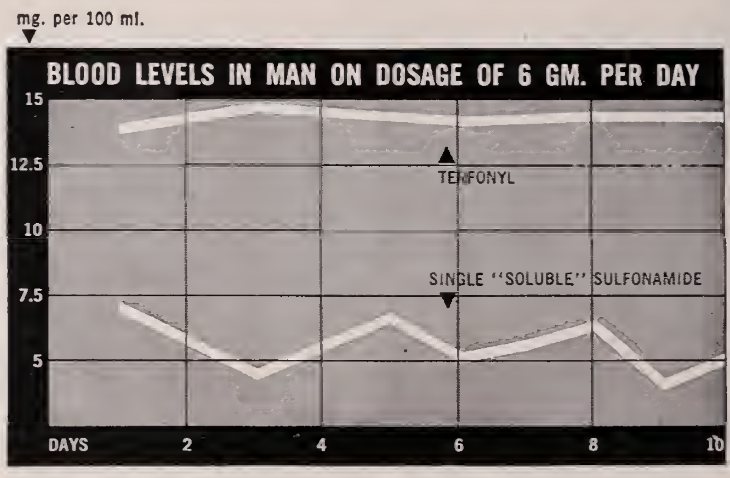
Terfonyl

SQUIBB METH-DIA-MER SULFONAMIDES



— After Lehr, D., Modern Med. 23:111 (Jan. 15) 1955.

Terfonyl is absorbed as well as single "soluble" sulfonamides, but is eliminated at a slower rate. For this reason, Terfonyl blood levels are much higher.

In experimental infections (Klebsiella, Pneumococcus, Streptococcus), Meth-Dia-Mer sulfonamides have been shown to be from three to four times more effective on a weight basis than single "soluble" sulfonamides.

Toxicity is minimal because normal dosage provides only one-third the normal amount of each sulfonamide. The body handles each component as though it were present alone, although therapeutic effects are additive.

Terfonyl Tablets, 0.5 Gm., bottles of 100 and 1000.
Terfonyl Suspension, 0.5 Gm. per 5 ml., pint bottles.

0.167 Gm. each of sulfamethazine, sulfadiazine and sulfamerazine per tablet or per 5 ml. teaspoonful of suspension.

SQUIBB

'TERFONYL'® IS A SQUIBB TRADEMARK

New Evidence on Rauwiloid®

confirms and defines superiority over other Rauwolfia preparations in the treatment of HYPERTENSION

- Rauwiloid represents the balanced, mutually potentiated actions[1] of several Rauwolfia alkaloids, of which reserpine and the equally antihypertensive rescinnamine have been isolated.
- Hence, reserpine is not the total active antihypertensive principle of the rauwolfia plant.
- Rauwiloid is freed of the undesirable alkaloids of the whole rauwolfia root. Recent investigations confirm the desirability of Rauwiloid (because of the balanced action of its contained alkaloids) over single alkaloidal preparations; "...mental depression...was...less frequent with alseroxylon..."[2]

The dose-response curve of Rauwiloid is flat, and its dosage is uncomplicated and easy to prescribe...merely two 2 mg. tablets at bedtime.

KARO® SYRUP . . . meets the need for an easily digested milk modifier

Since the newborn infant has very little ability to digest starchy foods, the carbohydrate requirements of the formula-fed baby are best met with a milk modifier which places a minimum demand on the digestive system.

Karo syrup has been a carbohydrate milk modifier of choice for three generations. Because it is a balanced mixture of dextrins, maltose and dextrose, it enables the feeding of larger amounts of total carbohydrate without producing gastro-intestinal disturbances.

Other characteristics that commend the use of Karo for milk modification are—the ease with which formulas may be calculated or prepared—its ready availability—and its economy. Light or dark Karo syrup may be used interchangeably with cow's milk or evaporated milk and water. Each fluid ounce (2 tablespoonfuls) yields 120 calories of solid nutrition.

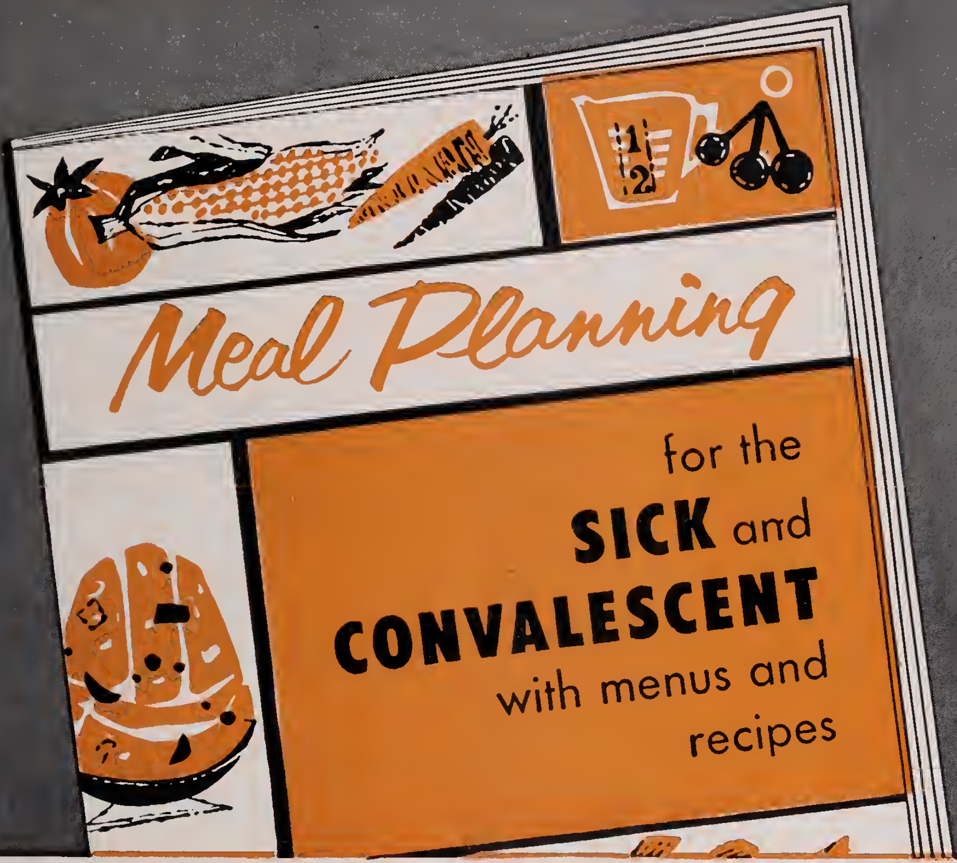
KNOX Protein Previews



New Booklet Presents
Latest Facts on Feeding the Sick

KNOX
UNFLAVORED
GELATINE

Adequate nutrition during illness and convalescence is essential for recovery whether the patient is managed in the hospital or at home. In the latter case, physicians often must devote much time to instructing those responsible for caring for the sick in good nutritional practices.

"Meal Planning for the Sick and Convalescent" has been designed to relieve you of the need for repeating over and over again essential dietary facts. This new Knox booklet presents in layman's language the latest nutritional applications of proteins, vitamins and minerals, gives practical hints on serving food to adults and children, suggests ways to stimulate appetite and describes diets from clear liquid to full convalescent. Best of all it offers the homemaker for the first time detailed daily suggested menus for each type of diet, plus 14 pages of tested nourishing recipes.

If you would like copies of this new timesaving Knox booklet for your practice, use the coupon below.

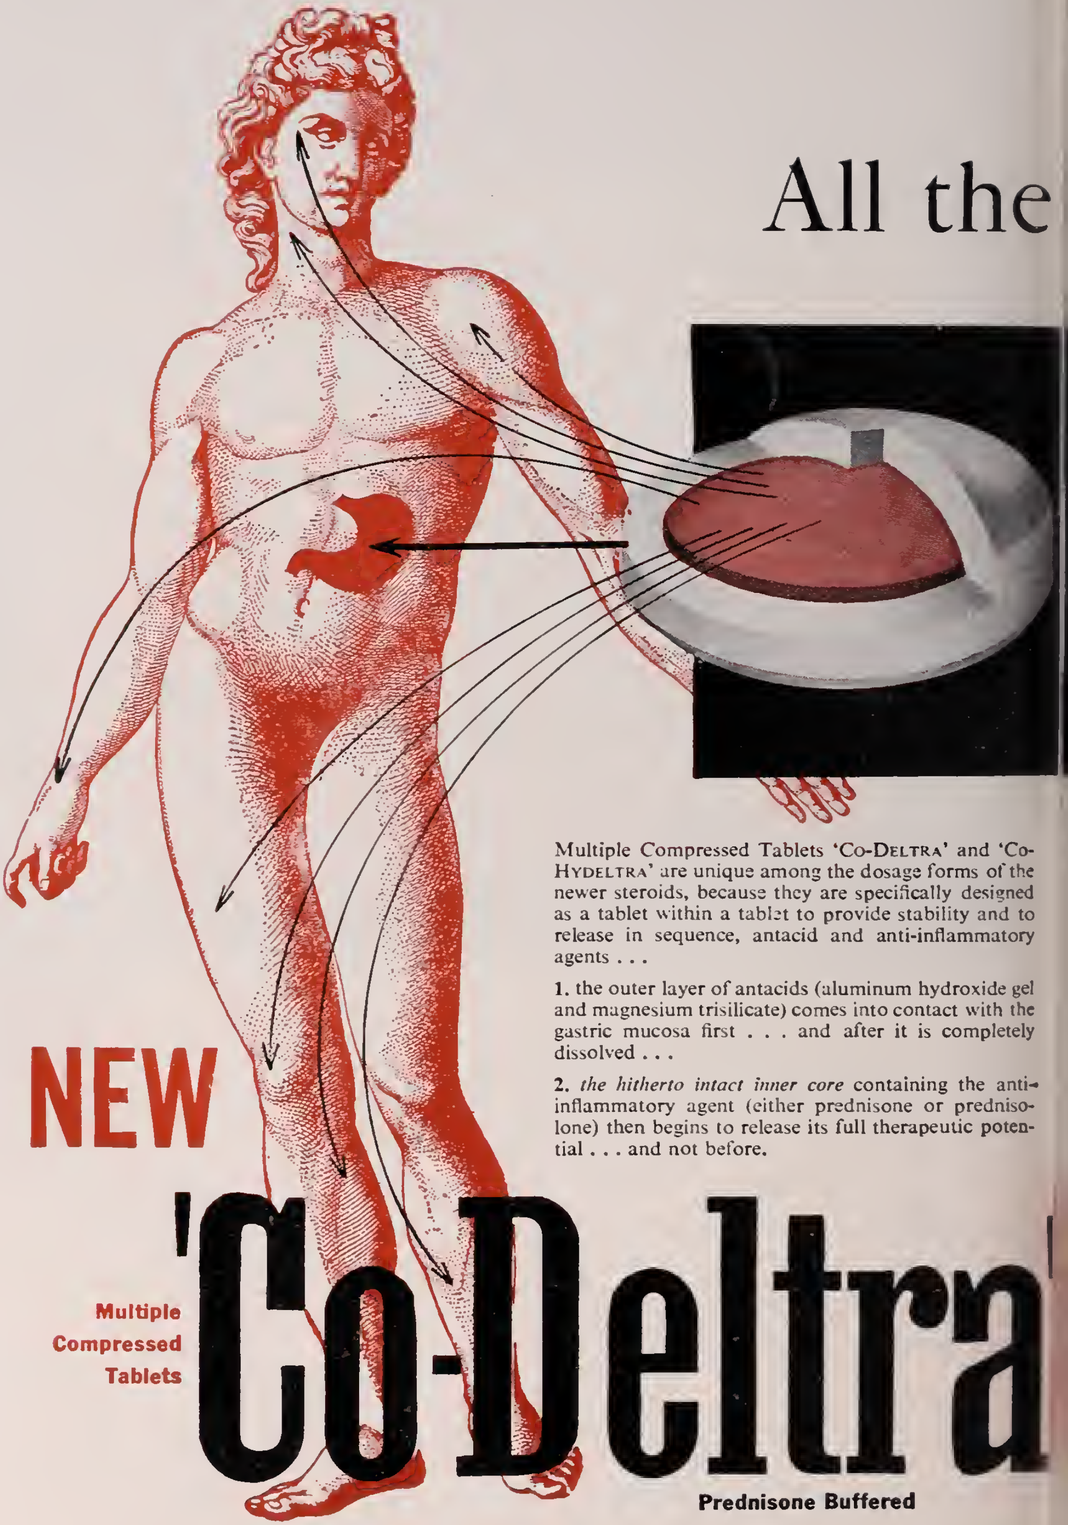
YOUR NAME AND ADDRESS

All the



Multiple Compressed Tablets 'Co-Deltra' and 'Co-Hydeltra' are unique among the dosage forms of the newer steroids, because they are specifically designed as a tablet within a tablet to provide stability and to release in sequence, antacid and anti-inflammatory agents . . .

1. the outer layer of antacids (aluminum hydroxide gel and magnesium trisilicate) comes into contact with the gastric mucosa first . . . and after it is completely dissolved . . .

2. *the hitherto intact inner core* containing the anti-inflammatory agent (either prednisone or prednisolone) then begins to release its full therapeutic potential . . . and not before.

NEW

'Co-Deltra'

Multiple Compressed Tablets

Prednisone Buffered

benefits of prednisone and prednisolone plus positive antacid action to minimize gastric distress...

A reportedly higher incidence of gastric distress in patients receiving the newer steroids prednisone and prednisolone indicates the desirability of co-administering non-systemic antacids.[1]

To help the physician cope with this problem of gastric distress which might otherwise become an obstacle to therapy with the newer steroids . . . Multiple Compressed Tablets 'Co-Deltra' (Prednisone Buffered) and 'Co-Hydeltra' (Prednisolone Buffered) are now available.

'Co-Deltra' and 'Co-Hydeltra' are now available in bottles of 30 on your prescription. Each Multiple Compressed Tablet contains:

Prednisone or Prednisolone, 5 mg.; 300 mg. of dried aluminum hydroxide gel, U.S.P., and 50 mg. of magnesium trisilicate.

'Co-Deltra' and 'Co-Hydeltra'
are trade-marks of Merck & Co., Inc.

Original Contributions

Biliary Stricture

J. BRADLEY AUST, M.D., and
RICHARD L. VARCO, M.D.
Minneapolis, Minnesota

A SIMPLE and inclusive definition of biliary stricture is difficult to formulate because the anatomical variations are so numerous. The types range from a localized stenosis, which the term “stricture” first brings to mind, to the complete urgical absence of most of the extrahepatic ducts. Inevitably, all stages between these extremes exist. Their clinical counterparts can be equally diverse.

Perhaps a stricture is best considered as a linical concept wherein obstruction of the extrahepatic biliary system other than solely from calulus, provokes one or more of the symptoms of aundice, cholangitis or pain. The etiological mechanisms can be congenital, neoplastic, inlammatory, or traumatic. As with most other persons writing on this subject, our interest in his study centers around those clinical instances rising from surgical injury. In this group of adult patients to be presented, all cases, save one, were of this traumatic type and occurred following he operations of cholecystectomy, cholecystostomy r choledochostomy. There was one case which ad had no prior operation. In this person the lesion was classified as of inflammatory origin.

History

Although the first references to biliary stricture ate from the French literature of the 1820's, when oth Andral in 1824[1] and Bauillaud in 1827[2] reorted this clinical symptom complex secondary o inflammatory and neoplastic causes, it was not ntil after cholecystectomy was introduced by Langenbuch[6] in 1882, and his contemporary urgeons used this procedure, that biliary strictures became a serious medical problem. One cannot isregard the coincidence between an increasing umber of gall bladder operations and a heightened prevalence of biliary strictures. Doyen, in 1892, was the first to report the use of end-to-end anastomosis for a divided common bile duct. Sprengel in 1891 recorded the successful anastomosis of the common bile duct to the duodenum. During the intervening years since then a wide variety of surgical techniques have been proposed and tried in order to re-establish the continuity of an injured extra-hepatic biliary duct either to itself or to the intestine. In 1918[4] and 1936[5] Eliot of New York, based on his collection of case reports from the literature, attempted to classify and evaluate the results of treatment in terms of the type of surgical repair. The experience at the Lahey Clinic was described in 1947 by Cattell,[3] and in 1950 by Lahey,[7] the latter reporting on 280 cases. There had been a two-year follow-up in 229 of them. This group achieved 73 per cent favorable results for either the end-to-end or the choledocho-intestinal anastomoses. Walters has summarized the surgical accomplishments with 254 biliary stricture cases. Choledochoduodenostomy was the most common operation at the Mayo Clinic from 1924 to 1947. Eighty-two per cent of these persons had satisfactory results.

Analysis of the Present Series

Between 1935 and 1955, seventy consecutive adults have been treated surgically for biliary stricture.

TABLE I. DISTRIBUTION OF SEX

Male	9
Female	61

TABLE II. DISTRIBUTION OF AGE

10-19	20-29	30-39	40-49	50-59	60-69	70-79
1	10	13	23	15	6	2

The sex and age distribution indicate that the average patient was a woman between forty and fifty years of age (Tables I and II).

From the Department of Surgery, University of Minnesota Medical School and the University of Minnesota ospitals.

We believe it is significant that two-thirds of all the persons afflicted were less than fifty years old. In this series, a young mother all too frequently was stricken while in reasonably good health. Ninety-five per cent (fifty-nine of the sixty-two cases available) have been checked upon as out-patients for at least two years after their last operation. Three patients have been lost to follow-up despite protracted attempts to contact them. An additional eight cases remain under observation for intervals up to two years. Questionnaires were sent to all available patients so that the information would be current. The family physician's appraisal of the patient's health was also sought.

The following classification of operative procedures was devised to catalogue the various methods employed in dealing with the biliary stricture problem at the University of Minnesota Hospitals:

I. Total external biliary fistula.
II. Partial external biliary fistula with T-tube.
  A. Stricture dilated and T-tube inserted through this area.
  B. Stricture incised and closed over T-tube.
  C. Stricture excised with T-tube bridging gap.
  D. Stricture excised with T-tube brought through the line of anastomosis.
  E. Stricture excised with T-tube brought out distal to line of anastomosis.
III. Internal biliary fistula.
  A. Choledochogastrostomy.
  B. Choledochoduodenostomy.
  C. Choledochojejunostomy.
IV. Dissection failure—i.e., failure to find the biliary duct proximal to the stricture.

The results have been classified as:

(S) Satisfactory
(I) Improved but with residual symptoms
(U) Unsatisfactory
(L) Follow-up inadequate (less than two years or lost)
(E) Expired

Our attempt at an evaluation of the results has been necessarily arbitrary. In the terminology used the distinction in a given case between a satisfactory and an improved result might be difficult or impossible. Any patient who has had previous unsuccessful attempts at surgical repair can show some liver damage as a result of recurrent biliary tract infection and obstruction. An otherwise effective anatomical result may then fail to resolve all lingering aspects of hepatic disease. The exact distinction between this result and a le
perfect biliary tract restoration in another patie
who has been without as much associated liv
injury, becomes conjectural. The "best" resu
the first individual could attain might have to b
scored as an improved result. The other thre
end result categories were usually more easil
determined; and, those patients with recurre
jaundice or cholangitis were obviously unsati
factory.

TABLE III. OVER-ALL OPERATIONS PERFORMED

Patients	70	
Operations elsewhere	104	
Operations here	109	
Total operations	213	3.04/pt.
Operations for stricture here	89	1.27/pt.

Table III lists the number of surgical pr
cedures, and as can be noted, each patient unde
went an average of three operations. In additio
to the original surgery, many persons had o
or more repairs prior to coming to the Universi
of Minnesota Hospitals. The discrepancy betwe
the number of operations performed here an
the number of operations for stricture performe
here arises from the need for additional surge
either for complications or for the sequelae of t
stricture operations. For instance, gastric resectio
for duodenal ulcer (probably) provoked by t
stricture and its consequences, was required in tw
individuals.

The symptom complex of jaundice and/
chills and fever following biliary surge
regularly identified for us the case as one with
stricture. All but six patients exhibited jaundi
on admission and three of these exceptions had
total external biliary fistula. The other three ha
been icteric upon prior occasion. Thirty-three
the seventy patients (47 per cent) came he
with chills and fever or had recently exhibit
these findings.

An analysis of the results of the several metho
of correction as attempted by a changing staff
the University of Minnesota Hospitals, sugge
certain considerations. The most common repa
attempted was an end-to-end anastomosis with
limb of the T-tube brought out through the line
the anastomosis (Table IV; II, D). Recurrenc
were common (and well-night predictable) aft
this procedure. The discharge of abunda
volumes of bile through the abdominal drai
during the postoperative period virtually assur
this likelihood. After the omission of those patien

ith an inadequate follow-up and the cases expiring postoperatively, only 40 per cent, or ten twenty-five persons so treated, had a satisctory end result. When the procedure was therwise comparable but for the simple expedient f bringing the T-tube out distal or proximal to he suture line, the outlook was distinctly more avorable (eight of eleven could be classified as atisfactory or improved) (Table IV; II, E). t is pertinent to note that this type of recontruction is possible (and probably successful) nly in persons with a localized stricture. Here he new union can easily be achieved without ither undue shortening or disruptive tension. uccess will depend also on having the duct iameters almost equal proximal and distal. We ere surprised to find that one individual with a ocalized stenotic type of stricture was satisactorily managed by a longitudinal incision and transverse closure. Mere dilatation of this ocalized type of stricture followed by the insertion f a T-tube was a long term failure in six of en attempts.

TABLE IV. CLASSIFICATION OF SURGICAL PROCEDURES

Results	I	II						III				IV
		A	B	C	D	E	Total	A	B	C	Total

ABLE V. OPERATIVE AND PATIENT MORTALITY

perations	Deaths	Per Cent
109	10	9.2
atient Mortality * (adequate follow-up)	15**	25.4

*Patients having two year follow-up.
*There were five late deaths considered due to stricture.

The results of choledochointestinal anastomosis ave been consistently better. Thirteen of sixteen 81 per cent) (Table IV; III, B, C) persons so reated secured a satisfactory or improved result. This percentage of succeses was even higher when he repair consisted of a choledochojejunostomy. The outcome in nine of ten such cases was satisactory. This result assumes additional significance if it is appreciated that this particular procedure (choledochojejunostomy) was often employed when other methods had proven unsatisfactory.

The consequences of dissection failures are self-incriminatory. Unless the technical problems were solved, the patient died.

TABLE VI. MORTALITY ANALYSIS

Type	Cases	Time	Cause
I. Dissection Failures	M.A.	P.O.	Failure to find proximal duct
	M.S.	P.O.	Failure to find stricture—biliary cirrhosis, hepatitis
	J.S.*	P.O.	Failure to find stricture—thought to have ca. of pancreas
II. Hemorrhages	C.B.**	P.O.	Hemorrhage
	M.F.**	P.O.	Hemorrhage and subphrenic abscess
	K.H.	P.O.	Hemorrhage
III. Infection***	A.E.	P O.	Peritonitis, subphrenic abscess, pancreatitis
	D.M.	P.O.	Liver abscess, biliary cirrhosis
	P.B.	P.O.	Liver abscess
	O.W.	P.O.	Pancreatitis, interstitial nephritis, bilateral atelectasis
IV. Late	A.B.	1 yr.	Hepatic artery injured and sutured at surgery—expired from ruptured aneurysm of hepatic artery.
	R.G.	13 yrs.	Expired following surgery for bleeding DU—extensive biliary cirrhosis.
	E.S.	6 mos.	Liver abscesses, suppurative cholangitis, recurrence of stricture.
	E.R.	6 mos.	Recurrence of stricture bleeding.
	M.R.	5 yrs.	Recurrence of stricture, biliary cirrhosis.

*Only case not having had previous biliary surgery
**Both cases prior to 1936
***All cases have been since 1942

The operative mortality (10/109—9.2 per cent) for this series of procedures is listed in Table V. The overall mortality of 25 per cent, including the late deaths to which the stricture contributed, emphasizes the gravity of this surgical problem. It is a benign lesion, but I don't think anyone would refer to it as a "benign condition." This is an unfair play on words.

A study of the deaths reveals four main causes:

TABLE VII. OVERALL RESULTS

	Number	Per Cent
Satisfactory (S)	34	48
Improved (I)	4	6
Unsatisfactory (U)	6	9
Follow-up inadequate (L)	11	16
Expired (E)	15	21
Total	70	100

dissection failures, hemorrhage, infection and late sequelae (Table VI). Two of three patients with fatal hemorrhage succumbed prior to the advent of vitamin K therapy. The deaths from infection occurred despite combinations of antibiotic therapy. Of the late deaths one seems attributable directly to the surgical procedure, while the other four arose as a consequence of the unresolved stricture problem.

Discussion

The tragic aftermaths of this iatrogenic affliction have been impressed upon us during the hours spent reading the often voluminous hospital charts of these patients. Effective prophylaxis against this regrettable situation is surely far superior to the best possible reconstructive procedure. The latter will always entail a period of pain and an element of anesthetic and operative risk that would not have been required had the initial procedure gone well. The experience of many surgeons, each having done more than a thousand operations upon the biliary tract without provoking this grave outcome, confirms the belief that the standard types of operations on the gall bladder should be devoid of such disasters.

We wish to avoid knocking into tree after tree while trying to get out of the forest, but do desire to attract attention to certain particularly distressing features of the common duct stricture problem. In two-thirds of the patients of this series, this tragedy fell upon women under fifty years of age. The expense to someone with a young mother away from home for a protracted interval during the mid-period of life, could scarcely be less serious economically were it to have happened to the wage-earning father. The other losses to the community and to the family are incalculable. Over and beyond the time spent in the hospital are often prolonged convalescent interludes, or, worse, those of recurrent partial disability. In yet other instances the patient never quite regains full health. Furthermore, undesirable residues of this condition are difficult to eliminate. Biliary cirrhosis, duodenal ulceration, portal hypertension from inflammatory obstruction, and yet other sequelae have developed in these people as a consequence of the common duct injury and the trauma secondary to attempts at its correction. The deadly seriousness of this problem is pointed up by the mortality of 25 per cent. These deaths, we believe, are largely ascribable to the stricture and/or to the subsequent procedures designed to correct it.

There can hardly be any reasonable opposition, it would seem, to emphasis on, and devotion to, the practice of those sugical techniques that will effectively prevent the occurrence of a common duct stricture. This is surely the challenging obligation in all centers training surgeons. The technical cautions to be observed are well described in the medical literature dealing with surgery for this area. Briefly, the operator must be indoctrinated never to divide any structure presumed to be the cystic duct until the common duct proper and the common hepatic duct have been thoroughly exposed and unquestionably identified. The apparent presence of anomalous structures should alert anew the prudent surgeon. Secondly, any untoward arterial bleeding from an inadvertently divided vessel should be managed by digital compression via Winslow's foramen while the specific leak is carefully sought for and forceps-point hemostasis secured. Inadequate dissection followed by clamping, cutting, and mass ligation before the complete identification of these specific ductal tributaries; indiscriminate, awkward, hasty, grasping instrumentation for a bleeding site in the portal hilus; and a common duct stricture is conceived. When this offspring, disturbing to contemplate, reaches full growth, few would care to acknowledge the paternity.

The next phase to be considered at this early stage in the growth of this problem child is the matter of affirming its existence. This diagnosis may become self evident, on an initial careful study of the history and corresponding work-up of the patient. Customarily, this identification will be more readily made by those persons less intimately involved with the creation.

There are certain clinical features supporting the diagnosis of a biliary stricture following a cholecystectomy. The development of very profuse, persistent bile discharge from wound or drainage site after cholecystectomy should alert one to the fact that the duct may have been severed. Those atients who become unremittently jaundiced and ave a minimal pigment content in the stools from he day of surgery henceforth, suggest that the uct has been tied off. Another identifiable group represented by those who recover from their nmediate surgery but sometime thereafter deelop the symptom complex of chills, fever and ght upper quadrant pain associated with icterus. 'hese late occurrences of stricture usually arise rom scarring at the site of a previous injury. Iere, as the fibrous tissue replaces the damaged iucosa the normal flow of bile is slowly throttled. t should be mentioned that this latter clinical icture can be perfectly simulated by choledochothiasis and operative exploration may be the only iethod of making a differentiation.

In the fallacious hope that an individual with stricture might spontaneously be cured through on-operative management, there is at times unue procrastination before electing effective surical therapy. This tendency is most pronounced ollowing a stricture repair that turns out unsatisactorily and the feeling waxes with one's memory f heightened tribulations during the previous fforts. Perhaps the responsible surgeon rememers these moments of trial and mentally rejects he unwelcome and ominous portent of recurrent hills, fever, and jaundice. This is indeed regretable, for biliary cirrhosis secondary to recurrent bstruction and cholangitis may progress to irreprable liver damage. In addition, recurrent bouts f cholangitis can so destroy the ductal mucosa hat a satisfactory repair becomes almost impossile. It seems wiser therefore to construe the onset f the above-mentioned symptom complex, following the removal of a T-tube or a similar splint, as recurrence of the stricture. With this decision nade, appropriate re-operative therapy is the raional course.

The obvious and traditional method of repair as been end-to-end anastomosis of the strictured luct. In its idealized form the normal anatomy is hereby restored. Though often technically diffiult, it can be accomplished, after a fashion, even vhen a large portion of the duct is absent. As ahey and his colleagues have shown, it is possible o expose the proximal common bile duct in the ubstance of the pancreas and, by mobilizing the luodenum, approximate the duct ends in a high ercentage of cases. With some temerity we sugest that perhaps the results would be superior if o frequent a recourse to end-to-end union were not employed as the method of choice—particularly in those cases where either a disproportion of stoma or tension exists. Moreover, if end-to-end anastomosis is used, our own experience as well as that of others indicates that any T-tube used must be brought out through a new opening in the duct wall well away from the lines of anastomosis. Proponents of end-to-end anastomosis contend that the sphincter of Oddi is essential for the prevention of intestinal content regurgitation into the biliary tract, if we are to avoid subsequent bouts of cholangitis for the patient. They, therefore, reserve choledocho-intestinal anastomosis for individuals in whom end-to-end anastomosis is not technically feasible.

Considerable evidence against this concept can be found in the evaluation of spontaneous, asymptomatic, internal biliary fistulas which cause no symptoms as long as they remain unobstructed. The experience of many surgeons has been that a choledocho-intestinal anastomosis does not cause cholangitis when this stoma remains free of obstruction. Finally, symptoms from this type of biliary tract drainage are habitually absent, when the operation is done for reasons other than stricture. Also in favor of the choledocho-intestinal union as compared to the end-to-end anastomosis, is the greater simplicity of the dissection. The surgeon has to find only the proximal end of the duct. The ease of the repair is likewise enhanced. The difficulties of precise end-to-end anastomosis where the duct ends are of unequal diameter are well known and evoke no surgical serenity in the post-operative moments of reflection.

We have approached this subject without rigidly preconceived ideas as to which technique might be the most satisfactory method of repair. With the evidence at hand we are now convinced that a uniformly superior result can be expected from a well-done, mucosa-to-mucosa, tension free, choledocho-intestinal anastomosis. Case analyses from both the Mayo Clinic and Lahey Clinic material reveal comparable accomplishment with either method, but the authors express the opinion that choledocho-intestinal anastomosis should be reserved for the more difficult of the stricture types, i.e., those in which end-to-end anastomoses are not practicable. The outcome in their hands was comparable, although they used the former preferentially in the worst cases. Because they noted as well that the choledocho-intestinal procedure was more easily performed, perhaps the choledocho-intestinal anastomosis should be re-evaluated. It may be the operation of choice rather than the method attempted only when end-to-end anastomosis is not easily done or has been recurrently unsuccessful. Admittedly, there are certain disadvantages to the Roux-en-Y type of choledocho-jejunostomy that is constructed without provision for bile re-entrance into the duodenum. This results in a form of the Mann-Williamson ulcer abetting operation. Two of our patients in this group subsequently required treatment for a duodenal ulcer. To avoid this, the jejunal limb can be re-anastomosed back onto the duedenum. On this basis and where technically possible, a choledocho-duodenostomy may be therefore the choledocho-intestinal operation of choice for biliary stricture.

From personal skirmishes with the biliary stricture problem a plan has gradually developed that has proved workable and useful. The procedure to be described carries no allegations of newness or originality but does possess for us advantages in surgical exposure and accomplishment that incline one towards its further testing.

Insofar as possible, prothrombin deficits are corrected and any serious contractions of blood volume and red cell mass are restored to normal values. The effectiveness of wide spectrum antibiotics is tested in all persons with fever and chills. Other antibiotic preparations capable of eliminating the usual bacterial flora of the intestinal tract are customarily but not always provided. An indwelling nasal gastric tube is connected to suction for several hours prior to the operation. This in combination with the antibiotics, permits the surgeon to work more advantageously in an abdomen where all the bowel within the visible limits freed by his dissection, is found to be stool free and collapsed.

A thoraco-abdominal incision well up the right seventh or eighth interspace and then transversely across the upper recti has much to recommend it. Once the diaphragm has been incised, the right lobe of the liver can be loosened from surrounding adhesions, delivered laterally and superiorly and dissection of the portal hilus is thereby considerably facilitated. By sharp instrument technique the hepatic artery and its major divisions are extricated from the surrounding scar tissue. The dissection is then approached from lateral to medial and begins at the lower edge of the right lobe of the liver. Any adherent duodenum or jejunum that was used in an earlier procedure should be cut free and next the overlying tissues cleaned away until the edge of the portal vein is quite evident. Now the residual of the common duct must be between these dissections and the surgeon need only remove the thickened hepatic capsule and cone out the intervening scar to yield the bile duct(s). We believe ultimate success in each case hinges on the surgeon's insistence on cutting far enough back on this structure so that all granulomatous, scarred, biliary tract is removed. Unless one makes this sacrifice of tissue back to good and healthy duct wall, a failure by restricturing becomes almost predictable.

Having developed by this amputation a fresh mucosal surface for the new stoma (or even up to three intra-hepatic duct ostia when it becomes necessary to curette that much liver away in order to secure an ample length of healthy bile tract), it can then be united mucosa-to-mucosa either to the duodenum or to a jejunal loop. For this anastomosis we prefer interrupted, fine (0000 or 00000) silk. At times it may be necessary to place the entire circumference of sutures, tagging each, before tieing a single one. Once the gut is approximated to the bile duct no room remains for accurate stitch placement. Final tacking bites approximate the serosal surface to the adjacent thickened liver capsule to minimize distraction across the suture line. No internal splints are usually inserted, for they are unnecessary if the anastomosis is well done. If it is not, serious leakage will occur postoperatively. A new stricture will almost surely develop. And, any tube through the anastomosis will provide scant protection against the bile peritonitis and none against the recurrent stricture. Furthermore, almost all tubes are provocative of some tissue reaction when in contact with a raw surface. Theoretically and perhaps practically, they are capable of inciting an excessive scarring tendency at the suture line.

Before completion of the operation, continuous catheter drainage is provided for the thoracic space and the entire incision closed with silk. All forms of abdominal drains are omitted. Throughout the dissection the bleeding may be steady and has an aggravating tendency to obscure the field. It further enhances the problem of identifying vital anatomical landmarks. Flushing these oozing surfaces with icebox cold, rather than warm

Ringer's solution will assist in controlling the seepage from the innumerable capillaries that have been divided. All blood lost should be replaced volume for volume. These procedures often require many hours of unhurried work. Time so spent becomes a rewarding experience when a successful result retrieves for the patient a health that has been devastated by a common duct stricture.

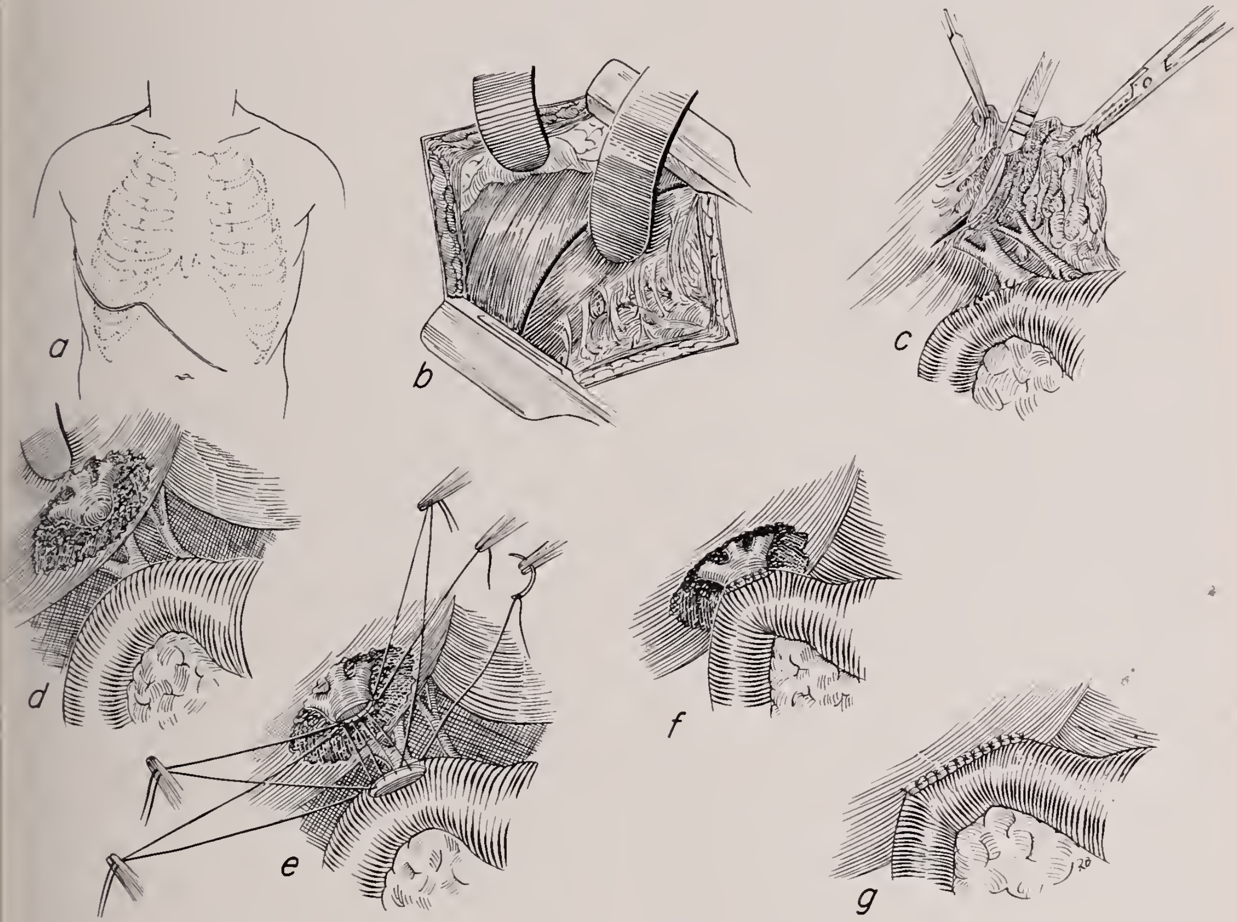

Fig. 1. Technique of exposure and repair of biliary stricture by choledocho-duodenostomy. (a) Line of incision. (b) Exposure showing right lobe of liver. (c) Dissection of hilus of liver to demonstrate portal vein and hepatic artery. (d) Coned out liver hilus to disclose blind end of biliary duct(s). (e) Placement of mucosa-to-mucosa stitches. (f) Completed anastomosis. (g) Buttressing layer duodenum to liver capsule.

Summary

1. The results of surgery for biliary stricture on seventy patients seen at the University of Minnesota Hospitals since 1935 have been reported.

2. It is again emphasized that this is essentially a preventable disease; it is responsible for significant patient morbidity, often demanding multiple operations, prolonged hospitalization, and sometimes produces a permanent disability. As well, there is a mortality rate as high as that recorded for many forms of gastrointestinal malignancy.

3. The traditional concept of end-to-end anastomosis with preservation of the sphincter of Oddi as the ideal form of treatment, is re-examined and questioned. Our results, as well as our analyses of the evidence from earlier publications show that equally satisfactory results can be obtained with choledocho-intestinal anastomoses.

Pigmented Villonodular Synovitis

A Clinical and Pathologic Study

WILLIAM G. ATMORE, M.D
Duluth, Minnesot
DAVID C. DAHLIN, M.D., an
RALPH K. GHORMLEY, M.D
Rochester, Minnesot

THE dark-brown to yellow villous and nodular projections from the synovial surface into a joint affected by pigmented villonodular synovitis produce a dramatic gross picture that is virtually pathognomonic of the condition. The relative rarity of this disease delayed an understanding of its pathologic evolution and natural history until the classic description by Jaffe and associates in 1941. A review of the literature and an analysis of their personal experience with twenty cases formed the basis of their article. Previous observers had recorded fifty-seven examples of the diffuse and circumscribed forms of pigmented villonodular synovitis of joints under a variety of names. There is no significant sex predilection for this disease, which, in its diffuse form, is common in young adults. The average age of the patients affected by the focal synovial lesions is older.

As just indicated, pigmented villonodular synovitis may affect the entire joint or may present as a focal tumor in an otherwise normal synovium. It may be debated whether the localized, often pedunculated, capsular or intra-articular growths are basically the same as the diffuse lesions. Evidence indicates that the tumor commonly called "xanthoma," or "benign synovioma of tendon sheaths," is only a different manifestation of the proliferative process in classic diffuse pigmented villonodular synovitis.[1-4] The focal lesions in the joint may look just like the characteristically solid tumors of tendon sheaths or they may be villous and spongelike, as in the diffuse lesions. Additional evidence that tenosynovial "xanthomas" and diffuse pigmented villonodular synoviti are closely related is the observation that th nodular masses in the latter disease are morphologically identical to the former. In rare instances,[1,5] bursae not connected with joints ar affected by a proliferative process of the typ seen in the diffuse articular lesions. This proliferative lesion involving the hip joint but presenting as a mass in the femoral triangle and a an intra-abdominal tumor has been reported.[6]

There are now slightly more than 100 recorded examples of pigmented villonodular synovitis o joints. The involvement was diffuse in somewhat less than half of these. All of the lesions were in the lower extremity. Except for six lesions in the hip[7-9] and seventeen in the ankle and tarsal bones,[1,3,10-12] all lesions involved the knee joint The extremely rare examples of bursal involvement have been seen in the region of the knee, the ankle and the iliopsoas muscle. More than half of tenosynovial "xanthomas" are in the fingers or at the metacarpophalangeal joints, while the locations next in frequency are the palms, wrists, toes, ankles, arms and legs.[13]

The cause and exact nature of pigmented villonodular synovitis and these related conditions are still unknown. Among the unproved theories is the concept that the process is a reactive inflammation of unknown origin.[1] Fisk[14] considered that the idiopathic syndrome of intermittent hydrathrosis is a precursor of pigmented villonodular synovitis. Equivocal evidence that the typical disease can be produced by injection of blood into joints has been presented.[15] Jaffe and co-workers[1] were unable to effect any appreciable permanent change in rabbits by this method. Bennett[16] has suggested that the reactive process of pigmented villonodular synovitis may represent a form of benign synovioma. Wright[17] stoutly maintained that the entire group of lesions already

---

Abridgment of thesis submitted by Dr. Atmore to the Faculty of the Graduate School of the University of Minnesota in partial fulfillment of the requirements for the degree of Master of Science in Orthopedic Surgery.

Dr. Atmore is from the Department of Orthopedic Surgery, Duluth Clinic, Duluth, Minnesota. Dr. Dahlin is from the Section of Surgical Pathology, and Dr. Ghormley is from the Section of Orthopedic Surgery, Mayo Clinic and Mayo Foundation, Rochester, Minn. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

mentioned is neoplastic, and he called them "benign giant-cell synoviomas."

Present Series

Our initial interest in pigmented villonodular synovitis was stimulated by the increased incidence of the disease at the Mayo Clinic in recent years. It was hoped that detailed study of the cases at the clinic might help to elucidate the cause of the condition and aid in determining whether a relationship exists between it and neoplastic disease of the synovium. It was elected to limit this study to pigmented villonodular synovitis as found in the joints and to two cases in which the process apparently was confined to popliteal bursae.

The cases in this series were obtained by examination of the pathologists' reports on all soft-tissue lesions of the lower extremity on file at the Mayo Clinic from January, 1920, to July, 1954. The review was limited to joints of the lower extremity because reports of articular pigmented villonodular synovitis above the hips could not be found in the literature. Any lesion reported to contain giant cells, iron pigment, foam cells or villous projections and involving a joint space was subjected to further study.

The gross specimens of any suggestive lesions, all of which were available for study, were then examined. New microscopic sections were prepared from various parts of all the specimens as indicated. A stain for iron was performed in each case.

Adding the cases gleaned from the files to the current cases, thirty-four examples of pigmented villonodular synovitis have been accumulated, including a recent typical diffuse lesion of the shoulder. The distribution is indicated in the table. The lesions in eighteen of the thirty-four cases were on the right side, sixteen being on the left. All thirty-two lesions involving joints were monarticular in nature.

The average age of all patients was 38.5 years. The age range in the patients who had diffuse articular disease was from sixteen to sixty years; six of these twenty-eight were included in each of the third, fourth and sixth decades of life and eight were found in the fifth decade. The ages of those who had focal lesions ranged from twenty to fifty-nine, and the two patients who had bursal disease were twenty-three and forty-six years of age, respectively.

TABLE I. PIGMENTED VILLONODULAR SYNOVITIS: DISTRIBUTION OF ARTICULAR LESIONS*

Location	Type of Lesion		
	Diffuse	Focal	Total Cases
Knee	20	3	23
Hip	5	1	6
Ankle	2	—	2
Shoulder	1	—	1
Total	28	4	32

*Excludes the two lesions confined to popliteal bursae.

The entire group showed a female sex preponderance of 23:11. In the patients with diffuse articular lesions, this ratio was 19:9.

Symptoms.—The average duration of symptoms before the patients came to the clinic was six and one-half years; the shortest period was six months and the longest was twenty-five years. Four patients had had surgical exploration elsewhere without definitive treatment. In two of these, popliteal bursae filled with pigmented villonodular lesions had been excised and similarly diseased knee joints with which they communicated had not been treated. Another, with no recognizable joint lesion, had undergone removal of the diseased popliteal bursa.

Pain was a complaint given by all thirty-four patients. The pain was severe and often incapacitating during periods of exacerbation of swelling, but generally it persisted as a dull ache between such episodes. Only four patients complained of pain in other than the involved joint. One of these had a punch biopsy of the opposite knee that revealed no pathologic changes, and another (the patient with the lesion of the shoulder) had a traumatic lesion of the other shoulder that explained the pain in the latter.

Swelling had not been noted by any of the patients who had lesions of the hip or shoulder. In contrast, all but one of those who had involvement of the knee or ankle mentioned this symptom, which had been noted at the onset of clinical symptoms in most instances. This swelling was intermittent and recurrent in fifteen patients, but progressive enlargement was present in twelve. Of the group with intermittent effusion, nine had undergone aspiration of the joint prior to treatment at the clinic. Three of these patients stated that the fluid had been hemorrhagic and two called it straw-colored.

Limitation of motion was a complaint in about half of this series. Three patients described recurrent "locking" of the involved joint.

Histories of trauma preceding the onset of symptoms were elicited from nearly half the patients.

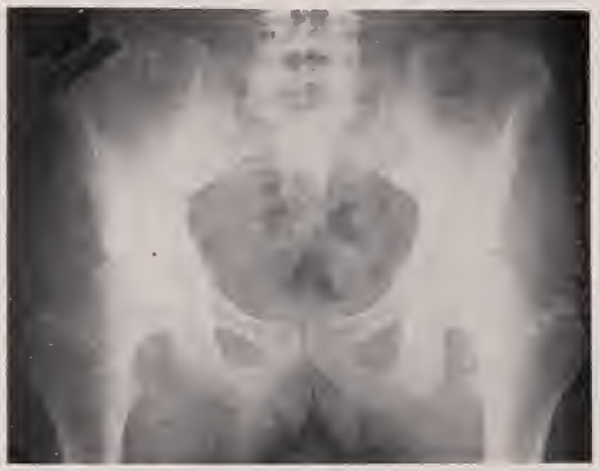

Fig. 1. Roentgenogram of the pelvis demonstrating cystic changes in the head of the femur and the acetabulum in pigmented villonodular synovitis of the right hip.

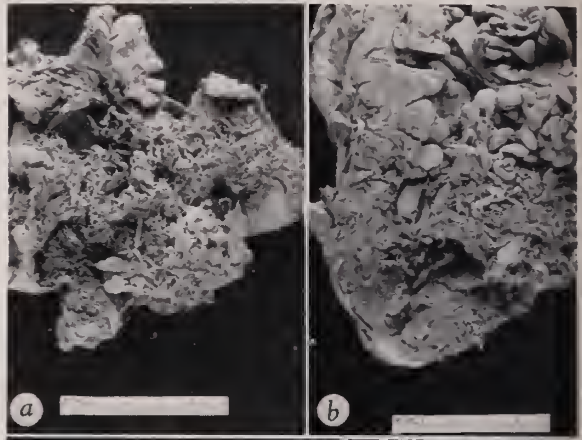
Examination.—Tenderness on palpation of the involved joint was present in half the patients. Limitation of motion, ordinarily minimal, but severe in a few, was recorded in twenty-one instances. Swelling of the affected joint was associated with all but one of the diffuse lesions of the knee or ankle; it was extremely prominent in several. This swelling was considered to be due to or associated with effusion in eleven patients. Focal masses in and about the joints were palpated in six patients. Enlargement of the suprapatellar pouch was observed commonly.

Roentgenographic examination gave positive results in two thirds of the diffuse lesions of the knee or ankle. Soft-tissue masses, sometimes nodular, were noted in thirteen of these twenty-two patients. Seven had cystlike rarefied foci measuring up to 2 cm. in diameter in the ends of the adjacent bones, two showed some irregularity of the bony cortex near the knee and one had only osteoporosis. All five patients with diffuse disease of the hip joint had cystic changes in their femoral heads and acetabula, along with other stigmas suggestive of degenerative joint disease of variable severity (Fig. 1). Two of the focal lesions of the knee produced soft-tissue masses visible roentgenographically, as did the lesion of the popliteal bursa that had not been excised.

Determinations of blood cholesterol, cholesterol esters, lecithin and fatty acids were done on five patients: all values were normal.



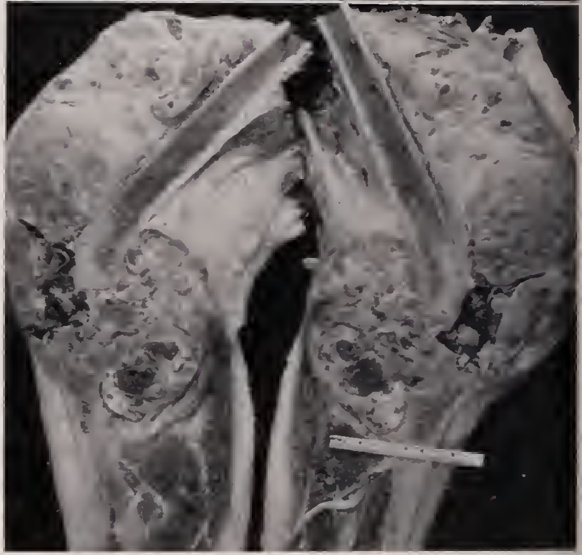


Fig. 2. *(above) (a)* Specimen from knee consisting mainly of shaggy villi, with minimal formation of nodules. *(b)* Lesion from knee demonstrating both villi and nodules.

Fig. 3. *(below)* Villonodular synovitis with pronounced tumefaction of the entire region of the knee joint, including the suprapatellar pouch. Because of severe destruction of the joint, amputation was considered the treatment of choice.

Gross Pathologic Appearance

A specimen obtained by punch biopsy through a trocar was the only tissue obtained from one patient. These brown shaggy fragments were accompanied by an excess of brown synovial fluid, such as was described in eleven of the surgically treated patients. Diffuse involvement of the joint in this patient was evident from the clinical features.

The pathologic process involved the synovium diffusely in twenty-seven of the patients treated surgically. The lesions in four patients were focal, with tan to dark-brown circumscribed masses varying from 2 to 13 cm. in diameter and projecting into the joint. Three of these focal tumors, unlike xanthomas of tendon sheaths, were spongelike, as though from partial fusion of villi. The largest lesion in this group filled a suprapatellar pouch. The uninvolved synovium in these patients appeared perfectly normal. The knee joint was the site of three focal tumors, and one was found in the hip.

The twenty-eight diffuse lesions included six in which there was extremely shaggy villous involvement, with only small nodules or none (Fig. 2*a*). The lesions in four of this group of twenty-eight patients were mainly nodular, with firm masses varying from 1 to 14 cm. in diameter and with thickening of the intervening synovium up to 2.5 cm. (Fig. 2*b*). The color varied from reddish brown to brownish black and many lesions had prominent yellow zones. The remaining lesions were both villous and nodular, with spongy regions of fused villi. Several of them contained small islands of normal-appearing synovium. One particularly remarkable specimen showed the entire region of the knee joint to be the site of a practically solid tumor measuring 30 by 20 by 20 cm. that had caused considerable destruction of the ends of the adjacent bones (Fig. 3). As already indicated, there were two instances in which popliteal bursae communicated with the knee joints and were affected by the same disease.

The other two lesions of the popliteal bursae showed diffuse villonodular disease similar to that noted in many of the articular lesions. In neither of these was there evidence of involvement of the knee joint itself.

Histopathologic Features

Microscopic study revealed a variety of characteristic changes. The most striking feature, in the average case, was hyperplasia of the synovial lining and stromal cells. This resulted in thickening of the lining layer and the production of thin or thick villous projections, with apparent penetration of these proliferating cells into the synovial connective tissue.

The villous projections ordinarily possessed cores of vascular connective tissue. These prominent synovial cells contained brownish pigment in every instance, although in some it was present in focal zones only. Special stains showed the brown pigment to be iron. Mitotic figures, present in every lesion and sometimes rather numerous. attested to the active proliferation of these cells. Occasional to fairly numerous multinucleated cells were found.

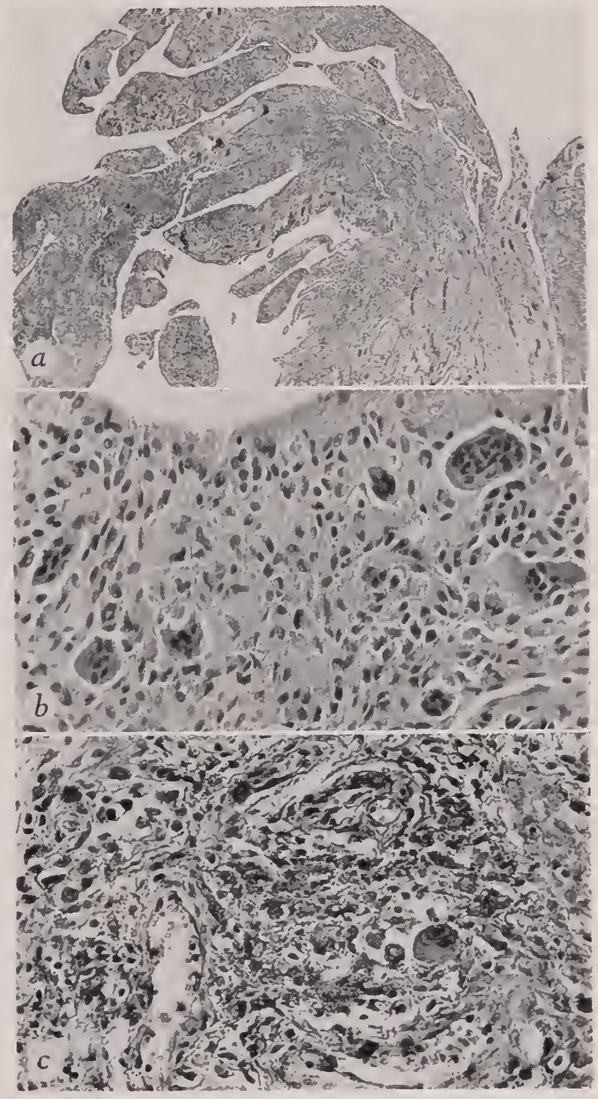

Fig. 4. *(a)* Villous formation and fusion of villi, with production of synovial-lined clefts (hematoxylin and eosin; x30). *(b)* Edge of a villous projection illustrating proliferating stromal and synovial cells and benign multinucleated cells (hematoxylin and eosin; x300). *(c)* Mass of synovial cells that are granular owing to the presence of hemosiderin (hematoxylin and eosin; x300).

As the lesions progressed in severity, fusion of these villous projections occurred, often producing prominent clefts lined by synovial cells (Fig. 4*a*). These clefts were present in every case and, when extensive, were the histologic counterpart of the spongy regions observed grossly. Solid zones with few or no residual clefts were seen in what appeared to be still older portions. These solid nodules were indistinguishable grossly or microscopically from xanthomas (benign synoviomas) of tendon sheaths. Their histologic components were proliferating synovial cells, benign multinucleated cells and cells containing variable amounts of iron or lipides, with occasional large hyalinized areas.

Lipides within isolated cells or sheets of cells were found in every lesion. When extensive, their presence produced grossly yellow zones. These lipide-containing cells were found commonly in the deeper portions of the synovial connective tissue. It was frequently impossible to decide whether the lipide-laden foam cells were basically synovial lining cells or histiocytic elements. Sheets of foam cells constituted a fourth or more of the histologic material studied in 75 per cent of the cases.

Multinucleated benign giant cells were present in every specimen (Fig. 4*b*). These ordinarily contained from eight to ten or more nuclei. They were found in both villous and nodular zones.

Iron pigment within cells also was found in every case (Fig. 4*c*). It was impossible at times to decide that the hemosiderin-containing cells were not histiocytes. To check the concept that extensive pigmentation is a feature of older lesions, the amount of iron found was correlated with the preoperative duration of symptoms. It was found that patients with extensive deposits of iron had experienced symptoms for an average of eight years, as opposed to an average of four years for those with less iron.

Cells usually associated with inflammatory changes were conspicuous by their paucity in these lesions. Occasional lymphocytes were seen in some areas. In only one instance were there focal and diffuse collections of lymphocytes to a degree comparable to that seen in rheumatoid synovitis.

Material from the adjacent cystic defects in the bones of a nearby joint was available for study in several cases. In none of these was the tissue from this source like the synovial lesion; rather, it consisted merely of myxomatous fibrous tissue of the type obtained from similar cysts in ordinary degenerative disease of joints. Furthermore, some of the cysts had no obvious communication with the joint space.

Treatment and Results

All four of the patients with focal lesions and one of the patients with a lesion of the popliteal bursa have remained well for periods varying from eight to thirty-four years after surgical excision. The other diseased popliteal bursa was removed one year ago.

The five patients who had diffuse lesions of the hip were treated by removal of as much of the diseased synovium as possible, followed by insertion of vitallium cups. Three had adjunctive roentgen therapy. These five were treated rather recently and have been followed for periods varying from six months to three and one-half years. Three have had good results, whereas two have considerable limp. These follow-up periods are, of course, inadequate for final appraisal. To date, there is no appreciable difference in results between the irradiated and the nonirradiated patients.

Eighteen of the patients who had diffuse lesions of the knee joint were treated with subtotal synovectomy, which consisted of removal of as much of the synovium as was deemed surgically feasible. Follow-up information for more than two years is available in only ten of these. Half of the ten had irradiation therapy in addition to excision. No significant differences are apparent in the long-term results from the two forms of treatment in these small groups. Recurrence has been proved in three of the ten patients and several others have some stiffness.

Results in the two patients who had diffuse lesions of the ankle likewise shed little light on the problem of correct management. One had subtotal removal and roentgen therapy that was repeated a year later because of persistent disease; he then was lost to follow-up. The other had excision of the bulk of the diseased tissue, followed by two courses of radium treatment. He received roentgen therapy three years later after excision of a recurrent lesion. Although the progress of the disease was arrested, amputation became necessary seven years after the second operation because of damage from the irradiation.

The lesion in the shoulder was recently excised, along with repair of a torn musculotendinous shoulder cuff. Apparently, it was merely an incidental finding despite its typical gross and microscopic features. The result was good eight months after operation.

Comment

The pronounced predilection displayed by pigmented villonodular synovitis for the lower exremities, especially the knee joint, was further emphasized by this study. As already indicated, however, a typical example of this disease was discovered just prior to completion of this review, as an incidental finding in the shoulder of a patient. Thorough perusal of the files on lesions of the upper extremity possibly might uncover more cases. We were unable to discover why this esion generally is limited to the lower extremity. Trauma was noted by nearly half the patients but, inasmuch as a history of notable injury generally is obtained readily in disease of the joints and extremities, it appears that trauma was an ncidental episode in these instances.

Sections of synovium taken from three knee oints containing hemorrhagic fluid after trauma were seen in the course of this study. The synovium in these instances contained hemosiderin n the lining cells and underlying histiocytes but ailed to show any of the other features of pigmented villonodular synovitis. This series lent no positive support to the view that the disease is caused by intra-articular hemorrhage. Furthermore, none of these patients gave evidence of any blood dyscrasia. It has been shown that hemochromatosis gives brownish pigmentation of he synovial lining not associated with the other eatures of pigmented villonodular synovitis.[18]

As indicated before, Fisk[14] mentioned the possibility of so-called idiopathic intermittent hydrarhrosis as a precursor of pigmented villonodular ynovitis. One third of our patients gave a hisory of recurrent effusion in the involved joint prior to operation, but it is impossible to determine any cause-and-effect relationship.

Some investigators have considered rheumatoid arthritis to be a precursor of pigmented villonodular synovitis. One of our patients had an inflammatory component suggestive of rheumatoid synovitis but, with this single exception, the study indicated no transition between these two diseases. Because the cases were selected for study on the basis of suggestive pathologic reports on file, numerous villous rheumatoid synovial membranes were studied. It appears unlikely that transitional phases between these two entities could have been overlooked if they occur.

The impression gained from the literature is that disordered metabolism of fat plays no significant role in this disease. Only five of the patients in this series had determinations of blood lipides, all of which were normal..

The question of whether pigmented villonodular synovitis represents a peculiar type of synovial neoplasm is as yet unanswered. Features suggesting that the lesion may be neoplastic include the following: In each of these patients, the disease was progressive until treatment was instituted. The nodules formed are identical to xanthomas of tendon sheaths, which some observers consider to be benign synoviomas. The large size that may be attained by these lesions in the absence of a significant inflammatory component is difficult to explain on a non-neoplastic basis. Furthermore, no infectious agent has been implicated.

Lewis[19] has listed criteria for the roentgenologic diagnosis of pigmented villonodular synovitis. These include (1) bones of a young adult, (2) monarticular involvement, (3) an excessive amount of synovitis, which may appear smooth in outline but which is particularly diagnostic when it is, in part at least, nodular in outline and density, (4) no indication of abnormalities of cartilage and (5) completely normal-appearing bones. This last criterion is frequently invalid, as evidenced by the number of lesions in this series in which cystic defects adjacent to the joints were seen. In fact, such cysts were observed in all the patients who had diffuse disease of the hip joint.

Aspiration of synovium for biopsy confirmed the diagnosis of pigmented villonodular synovitis in four cases in this series. These specimens were procured by the technique for punch biopsy described by Polley and Bickel.[20] In patients in whom the disease is focal and even in some of those with diffuse involvement, a specimen procured blindly through a trocar could fail to give unequivocal histologic proof of this disease; however, a diagnostic specimen should be obtained in most of the diffuse lesions of knee joints.

Histologic studies in this series revealed no new features. None of the lesions underwent malignant transformation. Mitotic activity may be prominent in parts of these lesions but an erroneous diagnosis of a malignant lesion, such as synovial sarcoma, can be avoided readily. The combination of iron-containing cells, lipide-containing cells and benign multinucleated cells labels this condition benign as accurately as it does in the case of xanthomas of tendon sheaths.

The two examples of pigmented villonodular bursitis re-emphasize the fact that this peculiar lesion can occur apart from joints.

The best treatment of diffuse pigmented villonodular synovitis is still debatable. Synovectomy frequently gives prolonged benefit but recurrence is not uncommon; recurrent lesions appeared after five years in two of our patients. Roentgen therapy has been advocated by some workers.[12,19] Our observations certainly do not justify a dogmatic stand but we are of the opinion that as complete surgical extirpation as possible should be attempted. Postoperative irradiation therapy may be advisable, especially in the management of recurrent lesions. Since no lesion in this series nor in the literature has pursued a malignant course, treatment is never an emergency procedure.

Summary and Conclusions

A series of thirty-four cases of pigmented villonodular synovitis has been studied at the Mayo Clinic.

Pigmented villonodular synovitis is a relatively rare disorder of unknown cause and nature. Without completely settling the issue, this study lends support to the theory that the lesion is neoplastic or at least can assume the proportions of a neoplasm.

These observations emphasize the histologic kinship of the diffuse and focal synovial lesions, as well as pigmented villonodular bursitis and "xanthomas," or "benign synoviomas," of tendon sheaths.

Study of this series and of reported cases indicates that further evaluation and follow-up data are necessary to determine the best treatment or combination of treatments for the diffuse form of pigmented villonodular synovitis.

Present Concept of the Treatment of Arteriosclerosis Obliterans

J. EARLE ESTES, JR., M.D.
Rochester, Minnesota

ARTERIOSCLEROSIS obliterans is a term used to designate a chronic occlusive arterial disease of the extremities occurring as a maniestation of atherosclerosis. The syndrome of areriosclerosis obliterans becomes manifest as a reult of ischemia of tissues owing to interference with the flow of blood through the main peripheral arteries. The treatment of this syndrome is complex because of its numerous clinical manifestaions and the lack of knowledge concerning its ause. The principles of therapy might be stated hus: (1) arrest the progress of the disease, (2) ttempt to increase blood flow in the ischemic issues and (3) provide symptomatic relief.

Arrest Progress of Disease

To arrest the progress of arteriosclerosis obliterans would require knowledge as to the cause of atherosclerosis. At present, knowledge of this is oo incomplete to provide an exact therapeutic regimen. Because of the obvious implication of abnormal metabolism of fat in the development of atherosclerosis, several therapeutic measures have been aimed at correction of this defect. These include, either singly or in combination, the provision of a diet low in fat content and the administration of lipotropic substances (inositol, holine), estrogens, thyroid extract, heparin, or odine, to mention only a few. To summarize this omplicated problem briefly, it is my opinion that here is no treatment that has been demonstrated o have a consistent effect in arresting the progress of atherosclerosis. One should discuss briefly and imply with patients afflicted with arteriosclerosis obliterans (and particularly when it is associated with hyperlipemia) the apparent relationship of at metabolism and atherosclerosis. Thus, the patient may participate in any decision as to treatment with a diet low in fat content or with drugs.

It has been shown conclusively that the quantity of nicotine in a cigaret produces vasoconstriction of the arteries supplying the skin and thereby results in decrease of blood flow and skin temperature. This vasoconstriction is likely to be harmful in ischemic extremities. Ordinarily, I urge patients with severe ischemia to discontinue the use of tobacco. However, in patients with only mild ischemia I merely discuss the role of tobacco in further decreasing their circulation, emphasize the medical reasons for discontinuing the use of tobacco and leave the decision on the use of tobacco to the patient. One must utilize a certain philosophic approach to this problem, for many times the complete discontinuance of the use of tobacco represents a hardship and loss of pleasure to an elderly person with minimal if any resultant medical benefit.

Control of trichophytosis is important, because this condition frequently causes interdigital fissures which may lead to cellulitis and gangrene. Ordinarily, soaking the feet in a 1:9,000 solution of potassium permanganate for 15 minutes twice daily is successful in eradicating trichophytosis in 5 to 10 days. After this has been accomplished, it is wise to suggest the daily use of a foot powder such as zincundecate (desenex) as a prophylactic measure.

Appropriate control of diabetes, when present, is important, for this measure aids indirectly in the healing of ulcers and in maintaining resistance to local infections.

Theoretically, long-term use of anticoagulant drugs should be beneficial in preventing the thrombosis of chronic occlusive arterial diseases. However, this treatment usually is not practicable because of the risk of hemorrhage, the need for adequate laboratory control of prothrombin time, the cost to the patient and the need for treatment to be continued over many months or years.

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minesota.

Attempt to Increase Blood Flow

Attempts to increase blood flow in ischemic extremities have been numerous and varied in type. My colleagues and I have not found postural exercises and the use of suction or pressure apparatuses sufficiently beneficial to warrant their use. The Sanders oscillating bed seems moderately helpful in increasing blood flow to the feet, relieving ischemic neuritis and inducing sleep. However, the use of such a bed is ordinarily confined to a hospital, although a few of our patients have purchased one for home use.

A warm environmental temperature is helpful in producing vasodilatation of the skin. Vasodilatation may be obtained by keeping the temperature of the patient's room between 85° and 90° F. My colleagues and I have also used a wooden box, placed at the foot of the bed, into which are placed the patient's lower extremities. The temperature in this box is kept thermostatically between 85° and 90° F. Contrast baths have been used in the past, but I prefer not to use these because of the possibility of trauma from excessive heat or cold. Also, whatever vasodilatation is produced by contrast baths is very transient.

One to two ounces of alcohol given three or four times a day produces transient vasodilatation, some sedative effect and mild euphoria. It should be remembered, however, that the effect is transient and that some people cannot tolerate alcohol. I hesitate to advise the regular use of alcohol over a period of weeks or months for fear of inducing a state of chronic alcoholism. At times, alcohol may be given intravenously as a 5 per cent solution, the rate of infusion being regulated by the effect on the patient.

"Vasodilating" drugs such as 3-pyridinemethanol (roniacol), benzazoline (priscoline), hydrogenated ergot alkaloids (hydergine), hexamethonium bromide (bistrium) and pentolinium tartrate (ansolysen), for example, have been advocated for the treatment of arteriosclerosis obliterans. Our experience has been that "vasodilating" drugs have not been significantly effective in increasing arterial blood flow in extremities that are ischemic owing to arteriosclerosis obliterans. Theoretically, the effectiveness of such drugs depends upon the capacity of the peripheral arteries to dilate. If a prominent vasospastic element is present, such drugs may be partially beneficial in reducing vasospasm, but this situation rarely is a significant factor in arteriosclerosis obliterans.

Lumbar sympathectomy is used at times in arteriosclerosis obliterans to increase the flow of blood through the skin. Such an increase occurs as a result of vasodilatation of the small arteries that supply the skin. Lumbar sympathectomy provides maximal "permanent" vasodilatation. It does not arrest the disease process that is causing arterial occlusion, nor does it open arteries that are organically occluded.

A bilateral, abdominal, extraperitoneal approach may be used in which some or all of the first four lumbar ganglia are excised. Ordinarily, the second and third lumbar ganglia are the ones excised, but if the first and fourth are visible in the incision they also are removed. When both second lumbar ganglia are removed, approximately half of the men so treated will be sterile. This occurs as a result of loss of ejaculatory power. Some of the men so affected regain the power of ejaculation after several weeks or months. Whether unilateral or bilateral lumbar sympathectomy is performed depends upon whether the occlusive arterial disease is unilateral or bilateral. Also, in some instances in which it is desirable to avoid sterility, unilateral lumbar sympathectomy is advisable.

There are no exact criteria for selection of patients for lumbar sympathectomy. In general, persons who are less than 60 to 65 years of age (and that is more or less an arbitrary figure), who have little or no gangrene and who seem clinically to have the potential for vasodilatation may be considered to be suitable candidates for the operation. One aid in selection of patients is to determine whether the skin temperature of the toes can be increased under conditions of vasodilatation. The vasodilatation is preferably induced by a room environmental temperature of 90° F., but may also be induced by ingestion of alcohol or by a lumbar sympathetic block with piperocaine (metycaine).

In general, neurosurgeons perform lumbar sympathectomy more often in younger than in older patients, in those without gangrene (unless very minor) and in those in whom the capacity for vasodilatation can be demonstrated. My colleagues and I do not advise sympathectomy in the presence of extensive ulcerations or gangrene in which amputation is likely to be necessary. Sympathectomy in such circumstances is ordinarily a needless operation.

In recent years, surgeons have attempted to produce chemical sympathectomy by injecting the lumbar ganglia with absolute alcohol. We do not feel that this procedure is adequate replacement for surgical excision of ganglia, because the effect is inconstant and transient in some instances. However, chemical sympathectomy may be used when surgical sympathectomy is not advisable, as in advanced age or in the presence of a disease that makes the surgical risk excessive.

Improved surgical techniques have led to attempts at improving blood flow to ischemic limbs by means of blood-vessel grafts. Initially, simple resection of the diseased segment of artery was performed. Some patients have demonstrated return of pulsations in the foot and decrease in severity of symptoms following such treatment. However, this form of therapy has not been uniformly successful. Resection of the diseased arterial segment in conjunction with placement of a vessel graft to replace the diseased segment and to provide continuity of the vessel has also been attempted. Types of grafts include homografts with vein or artery, and prosthetic grafts of nylon, orlon or ivalon. Vein grafts seem to be the least desirable because of a tendency to rupture or aneurysm formation. It is too early to evaluate completely arterial or prosthetic grafts but experience with both of these has been very encouraging. The beneficial results of grafting include restoration of the continuity of major vessels and pulsatile blood flow plus relief of symptoms. Most of these grafts remain patent and have not been associated with hemorrhage or aneurysm formation. This new surgical approach to the treatment of *segmental* arterial occlusion seems to represent a major advance in the treatment of arteriosclerosis obliterans. However, final evaluation of its efficacy must await statistical study of such surgically treated patients over a period of several years.

Relieve Symptoms

Symptomatic treatment of patients with arteriosclerosis obliterans requires the use of diverse therapeutic agents. A deproteinated extract of pancreatic tissue (depropanex) has been used in the treatment of claudication. Roughly, 50 per cent of patients treated with this substance feel that they obtain some improvement. Objective proof of this is lacking. This form of therapy may be justifiable occasionally, although I personally doubt its effectiveness. The dosage is empiric—5 cc. given intramuscularly each day for one week and then 5 cc. given intramuscularly three times a week for two weeks, two times a week for two weeks and once a week for two weeks. If the patient considers that claudication is decreased, the entire course may be repeated after a six-week interval.

Other drugs that have been used for claudication are curare, mephenesin (tolserol), heparin, testosterone and nicotinic acid, but they have been of no significant benefit in our experience. Achilles tenotomy has been advocated for relief of claudication, but this has not been universally accepted. Bilateral tenotomy results in a shuffling gait and requires re-education in walking.

Relief of pain of ischemic neuropathy may be difficult. One should use the simplest drugs first, such as barbiturates, aspirin and codeine. Often, however, it becomes necessary to use opiates such as morphine or meperidine (demerol). Physicians must be extremely cautious to avoid addiction in such patients. Rarely, in cases in which it is not possible to relieve a severe, chronic ischemic pain amputation is justifiable.

The rôle of trauma in the causation of ulceration and gangrene cannot be overemphasized, and patients with ischemic extremities must be instructed as to the care of their feet. They should be cautioned to wear well-fitting hose and shoes, and to avoid all forms of trauma (thermal, chemical, cutting, bruising and so forth). Corns and calluses should be cared for by a physician or a well-trained chiropodist who is aware of the problem of ischemic feet. Toenails should be cut squarely and ingrown nails treated by a physician or chiropodist. Fungous infections must be controlled.

Ulceration and gangrene require rest in bed. The area to be treated may be cleansed by using wet boric acid packs continuously. A 0.5 per cent solution of aluminum subacetate is helpful for pruritic lesions. Dilute acetic acid is particularly beneficial in ulcers infected by Pseudomonas organisms. Wet tyrothricin packs are also helpful in some instances in which the infection of the ulcer is resistant to other measures.

Suction Drainage for the Prevention of Dead Space in Surgical Wounds

S. R. MAXEINER, JR., M.D., and
STANLEY R. MAXEINER, M.D.
Minneapolis, Minnesota

FUNDAMENTAL surgical principles indict dead space as an obstacle to healing. Accordingly, surgeons have made special efforts to prevent serosanguinous accumulations consequent to the leaving of unfilled spaces in the depths of wounds. The thoracic surgeon knows that the best prevention of empyema after thoracotomy is full expansion of the lung to fill the chest. The plastic surgeon lays as much emphasis on a good pressure dressing as on the surgical procedure proper. He soon becomes fully aware of the frequent difficulty in keeping the pressure uniformly and accurately applied despite irregular contours and motion. The general surgeon has frequent occasion to create extensive wounds which have potential spaces for the accumulation of blood and exudate. Of especial note are the operations of radical mastectomy, block dissection of the neck, radical inguinal dissection, and ventral hernioplasty. Extensive flaps are elevated and finally replaced over raw surfaces which may ooze both blood and lymph. Should the potential space become filled with these fluids, infection and delayed healing are to be expected; prevention of such accumulation, although difficult, is the only road to primary healing. The purpose of this paper is to call attention to a simple technique to accomplish this end.

The principles of the procedure are to provide active external siphonage of fluid accumulations and to substitute atmospheric pressure for pressure dressings. All that need be done is to make the wound airtight and to drain the potential dead space under the flaps into a system having a pressure less than atmospheric.

After operative dissection, hemostasis, and repair in the usual fashion, a tiny stab wound is made at an appropriate point in the skin. Through it is passed a tight-fitting catheter having multiple perforations in its distal end. The catheter is placed under the flap in position to be maximally effective in the removal of fluid and air. One or more catheters may be used. The wound is now closed in the usual manner by any simple stitch. The closure of the space under the flaps should now be airtight. The wound is dressed lightly with collodion or aeroplast in order further to prevent leakage of air. The catheter or catheters are connected to sterile suction apparatus; a negative pressure of about five pounds per square inch is applied. At once the air and fluid under the flaps will be extracted; the flaps will be seen closely to conform to the underlying tissues, however irregular they may be. Suction is continued either by an electric pump or by the Wangensteen apparatus for a period of forty-eight to ninety-six hours. After this period of time, the returns will be minimal, the flaps will be adherent to their subvirons, and the catheter will be plugged with fibrin. At this time it can be removed.

A light dressing is now desirable until healing is completed. We have found that such dressings after radical mastectomy can be easily and comfortably held in place, without adhesive, by the wearing of a Muller chest binder.

We have been eminently satisfied with this technique after radical mastectomy. The bulky and expensive pressure dressing is entirely done away with, along with its odor. Flaps become promptly and securely attached to underlying tissues, even in the apex of the axilla. Healing is improved. Arm motion is regained earlier and more easily. Patients are ready to leave the hospital three to five days sooner than with prior techniques. We have had two patients subjected to a second radical mastectomy; both patients vastly preferred the suction technique.

There have been no ill effects noted from the application of negative pressure to wounds. Circulation has not been interfered with. Infection has been no problem.

The idea of suction-drainage is not original with us. In 1952, Raffl[5] described, after radical mastectomy, the use of a catheter passing from the potential dead space to a suction device. Koontz[4] used and described a similar technique in extensive ventral hernioplasty. The present authors became aware of the technique as it was employed at the U. S. Naval Hospital, Oakland, California, with very successful results, by Capt. Richard S. Silvis, U.S.N. Other favorable experiences have been reported.[1,2,3,7]

It should be specifically pointed out that these techniques differ from the simple application of suction to a drainage tube, especially a sump drain or a drain supplied with an air vent. In suction-drainage, the wound is made airtight. Because of the negative pressure thus created, complete removal of fluid drainage is secured; formation of further fluid is minimized by the uniform pressure of the atmosphere on the flaps; and primary healing of the approximated surfaces of tissue is promoted.

Summary

On the basis of our experience to date, we feel that suction-drainage of an airtight wound is the definitive technique for obliterating dead spaces in extensive surgical wounds.

PRESENT CONCEPT OF THE TREATMENT OF ARTERIOSCLEROSIS OBLITERANS

(Continued from Page 205)

It is suggested that the simplest measures be tried first. Application of any substance that might cause chemical necrosis is to be avoided. When the base of the ulcer is clean, a powder of dried erythrocytes may be sprinkled over the ulcer. After three to seven days, this may be soaked off and new powder applied. We have found this to be quite beneficial in some instances.

The use of a combination of streptokinase and streptodornase (varidase) has been found recently to be successful in producing a clean base of granulation tissue. The parenteral or oral administration of antibiotic drugs is frequently indicated for control of infection in the tissues surrounding the ulcer or the site of gangrene.

When therapeutic measures fail to heal the ulcer, amputation may become necessary. Before resorting to this, all conservative measures should be tried, if there seems to be a reasonable chance for healing to occur. Amputation of a gangrenous toe with subsequent healing of the amputation site is rarely possible in arteriosclerosis obliterans because of the severity of ischemia in this disease. The site of amputation (either "below knee" or "midthigh") is determined by the level of the extremity at which circulation is sufficient to permit healing of the stump. Many tests have been devised to localize such levels, but usually the surgeon can tell best at the time of operation by the amount of bleeding present. For example, if there is minimal bleeding in a below-knee approach, the surgeon may feel it necessary to do a midthigh amputation.

It is obvious from the above discussion that current therapeutic measures for arteriosclerosis obliterans are inadequate. The essence of the problem is that of the etiology of atherosclerosis. For when we learn to prevent atherosclerosis, its ischemic manifestations (arteriosclerosis obliterans) will no longer occur.

Minnesota Rheumatic Fever Survey, 1955

D. S. FLEMING, M.D., M.P.H.
F. J. HIRSCHBOECK, M.D.
J. A. COSGRIFF, M.D.

THE Minnesota rheumatic fever survey originated in 1953 when the Heart Committee of the Minnesota State Medical Association appointed a small group to prepare a brief questionnaire with the intention of learning from practicing physicians throughout the state how much of a problem rheumatic fever represented. The Minnesota Heart Association and the state health department participated in the project from its onset.

TABLE I. CASES OF RHEUMATIC FEVER REPORTED TO MINNESOTA DEPARTMENT OF HEALTH, 1944-1954

Year	Number of Cases
1944	0
1945	15
1946	82
1947	144
1948	120
1949	131
1950	162
1951	170
1952	221
1953	235
1954	148

Reasons for such a survey lay in the need for current information on rheumatic fever. In recent years a growing feeling has developed that rheumatic fever has been declining in incidence and prevalence and that the disease no longer is a serious problem. At the same time, newer methods of prevention and treatment have rapidly developed, deserving widespread adoption if the disease continues to be widespread. Because accurate current information as to the prevalence of the disease has been lacking, the Heart Committee undertook a statewide survey to provide some of this data.

In Table I is shown the number of cases of rheumatic fever reported to the state health department in Minnesota in the years since 1944 when the disease was made reportable. The cases reported in 1954 and 1953 are shown by age grouping and sex in Table II. Fifty-four per cent of the cases were in males. Of the 233 cases where age is given, 117 (50.2 per cent) were under the age of fifteen years. In these two years, 1953 and 1954, reported cases from fifty of the state's eighty-seven counties were recorded.

TABLE II. CASES OF RHEUMATIC FEVER REPORTED TO MINNESOTA DEPARTMENT OF HEALTH, 1953, 1954, BY SEX AND AGE GROUP

Age	1953			1954

Not stated	41	46	87	35	28	63
Total	124	111	235	84	64	148

The plan of the survey was to send to every physician in the state a simple questionnaire for his completion and return in a stamped return address envelope (see reproduction of questionnaire). Negative replies were indicated as important as positive replies. A letter explaining the survey and type of data requested accompanied the questionnaire. The definition of a case of rheumatic fever for purposes of counting in the survey was the responsibility of each physician to decide. The survey was directed at rheumatic fever as the doctors working diagnosis, and was not limited to rheumatic heart disease.

The questionnaire and explanatory letter were sent on September 9, 1955, to all physicians whose names and addresses were currently available to the Minnesota State Medical Association as members of the association; this group included 200 life members and totaled 3,063 physicians. This

Dr. Fleming is director, Division of Disease Prevention and Control, Minnesota Department of Health. Dr. Hirschboeck is chairman, Heart Committee, Minnesota State Medical Association. Dr. Cosgriff is president, Minnesota Heart Association.

To: Members of the Minnesota State
Medical Association

Dear Doctor:

The Heart Committee and the Council of the Minnesota State Medical Association asks your co-operation in a statewide survey of the present-day problem of rheumatic fever. We want you to tell us, on the enclosed simple questionnaire, how extensive a problem this disease is to you in your own practice, so that we will have a better foundation for approaching it on a statewide basis.

Rheumatic fever is reportable to the State Board of Health in Minnesota but because of difficulty in defining what is a reportable case, such figures over the years are neither complete nor entirely accurate. Even so, 235 cases were reported in 1953, and 150 cases in 1954. There is an impression that rheumatic fever is declining and is not a serious problem in Minnesota, but we need more complete information before we can accept this.

For the purposes of this questionnaire we leave the definition of active rheumatic fever up to you as a physician. If you are treating someone for this diagnosis, please count it for your entry to query 1. The data should include all cases under your care in the previous twelve-month period. We did not intend, however, that this entry would include patients being treated only for decompensation, resulting from rheumatic heart disease of the past. If the rheumatic fever is still an active part of the condition, however, such a case should be counted. You can see the problem of definition.

In query 3, as to kind of prophylaxis, we had in mind whether you employ some of the following measures:

Continuous prophylaxis for some patients.

Intermittent prophylaxis for some patients, by special treatment of acute attacks of streptococcal disease.

Special provisions of prophylaxis for patients admitted to hospital where there may be increased hazards from streptococcal contacts.

Oral prophylaxis.

Intramuscular prophylaxis.

Type of drug employed, such as sulfonamide, penicillin, broad spectrum antibiotics, other.

Several of these entries could all be included in answering query 3.

Please fill in the questionnaire now and return it to us in the enclosed stamped return addressed envelopes. If you have no patients in any of the categories listed, please tell us that, too. Negative answers are just as important to us as positive. Thank you very much for your prompt co-operation.

F. J. Hirschboeck, M.D.

QUESTIONNAIRE FOR RHEUMATIC FEVER SURVEY

(Date) ....

To: All Physicians in Minnesota

Please complete the following queries and return this sheet to the Minnesota State Medical Association in the attached return address envelope.

1. How many patients in your practice are you now treating for active rheumatic fever in the past twelve months?
2. How many patients are under 15 years?
3. How many individuals in your practice are you now giving some form of prophylaxis to, to prevent the development of rheumatic fever? ....
4. What kind of prophylaxis are you using?...............

....

(Signed) ...., M.D.

Address ....

County ....

Please check type of Practice:

Internist ———
Pediatrician ———
General ———
Surgeon ———
Other ———

Please answer at once.

group represents practically all physicians in Minnesota, whether practicing or not.

The response to the survey quickly became apparent as participation by physicians exceeded expected results. By December 1, a total of 1,556 questionnaires, 50.8 per cent of those sent out, had been returned. Of the total replies, 601 doctors, or 38.6 per cent, reported one or more cases of active rheumatic fever in the last twelve months; that is, a positive report to question 1. Four hundred and eighty-one (30.9 per cent) reported one or more cases of active rheumatic fever in children under fifteen years of age; and 649 (41.7 per cent) reported giving currently some form of prophylaxis to one or more individuals in their practice to prevent the development of rheumatic fever. It is apparent that participation in the survey was not limited to those physicians reporting positive findings only, as negative reports constituted from 58 to 69 per cent of all replies received.

Participation likewise was surprisingly similar by physicians in all parts of the state. Over-all, 50.8 per cent of physicians replied to the questionnaire. When these replies are grouped by counties and compared to the number of physicians to whom the questionnaire was sent in each county, it is apparent that this same percentage participation existed with only slight variation through the entire state. Replies were received from physicians in every one of the eighty-seven counties in the state. The percentage response from the four counties with largest numbers of physicians queried is shown in Table III. These four counties, with 59.5 per cent of all physicians

TABLE III. PARTICIPATION IN SURVEY BY PHYSICIANS IN HENNEPIN, RAMSEY, OLMSTED, AND ST. LOUIS COUNTIES

County	Number of Physicians Queried	Number of Replies	Per Cent Participation
Hennepin	864	476	55
Ramsey	438	210	48
Olmsted	370	142	38
St. Louis	152	106	69
Total	1824	934	51%

queried, returned 60.2 per cent of all replies received. It is apparent, therefore, that the survey results are not disproportionately weighted by the data furnished by physicians in metropolitan areas of the four counties listed above.

Thirty-seven replies, 2.3 per cent of the total, were received from physicians outside the state, whose names and addresses were on the mailing list as members of the Minnesota State Medical Association. These replies have been included in the data bearing upon participation by physicians in the survey but will not be included in data relating to the prevalence and incidence of the disease as reported in the state.

A further test of the validity of the survey findings lies in the participation by doctors carrying on various types of practice. Conceivably specialists in pediatrics, for example, might not have participated in the survey, while surgeons might have uniformly returned questionnaires. Table IV indicates the representation from various types of practices. Unfortunately no figures are available for the total number of doctors in Minnesota falling into the above types of practice, for comparison with the participation figures given. It does not seem unreasonable, however, to assume that roughly 4 per cent of all doctors practicing are pediatricians; 11 per cent, internists; and 45 per cent, general practitioners. If this is accepted, then the participation figures in the survey indicate that a representative sample of all practices responded to the questionnaire and that the data reported is safely acceptable from this standpoint.

The relatively large number of replies from physicians falling into the "other" category of practice, 440 (28.2 per cent) seemed somewhat unusual. As the individual replies were examined more closely, however, this impression lessened. Into the "other" category were placed replies from interns and residents, obstetricians, gynecologists, psychiatrists, urologists, eye, ear, nose, and throat specialists, allergists, proctologists, public health physicians, pathologists, x-ray and radiology physicians, dermatologists, and several other categories of physicians who would not normally diagnose or treat rheumatic fever. It appears that almost 30 per cent of all physicians in the state have no particular chance of contact with patients with this disease. It may be that this fact has contributed to the impression among physicians that rheumatic fever is no longer a serious problem.

TABLE IV. PARTICIPATION IN SURVEY BY VARIOUS TYPES OF PRACTICES

Type of Practice	Number of Replies	Percentage of Total
Internist	173	11.1
Pediatrician	62	4.0
General	713	45.8
Surgeon	168	10.7
Other	440	28.2
Total	1556	99.8

Data reported on the survey questionnaires, however, appear to show that rheumatic fever is currently a serious problem, both in terms of number of active cases, and in terms of number of persons receiving some type of prophylaxis. Replies from out of state physicians have not been included in the following data.

Fifteen hundred and nineteen physicians reported that they were currently treating, or in the last twelve months, had treated, as active rheumatic fever cases, a total of 2,297 patients. This represents a ratio of 1.51 patients for every reporting physician. When compared to the state's population, estimated for April 1, 1954, as 3,138,872, active rheumatic fever cases were reported at a rate of .73 per 1,000 population. Of the total, 2,297 cases reported, 1,434 (62.4 per cent) were indicated to be under fifteen years of age. When these cases are compared to the state's population under fifteen years of age, given as 823,899 in the 1950 federal census, and estimated in 1954 from school census figures as 934,032, active rheumatic fever cases under fifteen years of age were reported at a rate of 1.5 to 1.7 per 1,000 population.

Of the 1,519 physicians submitting replies, 597 (39.3 per cent) reported treating patients for active rheumatic fever. Their patients totaled 2,297 persons, an average of 3.8 cases for each physician reporting cases. When these figures are arranged by type of practice of the reporting physician, as in Table V, it is seen that pediatricians on the average report relatively more patients than do other physicians, with general practitioners and internists reporting about the same average number of patients. The figures for surgeons are perhaps too small to be reliable. Cases of rheumatic fever were reported from eighty-two of the eighty-seven counties in the state. The five counties not reporting cases, Cook, Dodge, Kanabec, Lac Qui Parle, and Red Lake, are rural areas not heavily populated. One reply was received from each of four counties, and two physicians reported from the fifth county.

TABLE V. REPORTED CASES OF ACTIVE RHEUMATIC FEVER, ALL AGES, BY TYPE OF PRACTICE

Type of Practice	Questionnaires Returned	No. of Positive Replies	Number of Cases	Average	Per Cent of Total
Internist	173	73	258	3.5	11.2
Pediatrician	62	45	242	5.3	10.5
General	707	456	1725	3.8	75.0
Surgeon	166	12	48	4.0	2.0
Other	411	11	24	2.1	1.0
Total	1519	597	2297	3.8	99.7

In comparing the numbers of cases reported from various counties, there do not seem to be great differences in the over-all rate from one area to the next. Because only a fraction of the physicians in the state responded to the survey, although this fraction is 50.8 per cent, it is unwise to expect that individual county reports of cases would give reliable rates of the incidence of rheumatic fever in single counties. In such instances, with low county population figures, the presence or absence of a report from one physician in the county would greatly influence the apparent rate. When counties are grouped together, however, into population units of approximately 250,000 and by location in the state, comparative rates of reported cases can be calculated with improved usefulness. Table VI shows this data for groups of counties comprising the eight District Health Units of the state health department.

TABLE VI. REPORTED CASES OF RHEUMATIC FEVER, RATE PER 1,000 POPULATION BY DISTRICTS

District	Headquarters	1954 Estimated Population	Number of Cases	Rate per 1,000 Population
I	Bemidji	227,164	141	0.62
II	Mankato	269,976	273	1.01
III	Rochester	329,853	238	0.72
IV	Duluth	285,438	159	0.55
V	Worthington	227,423	184	0.81
VI	Minneapolis	1,308,909	944	0.72
VII	Fergus Falls	220,812	143	0.64
VIII	Little Falls	269,297	215	0.79
	Total	3,138,872	2297	0.73

Counties in District I: Beltrami, Cass, Clearwater, Hubbard, Itasca, Kittson, Koochiching, Lake of the Woods, Mahnomen, Marshall, Pennington, Polk, Red Lake, Roseau; District II: Blue Earth, Brown, Carver, Faribault, Le Sueur, Martin, McLeod, Nicollet, Scott, Sibley, Waseca, Watonwan; District III: Dodge, Fillmore, Freeborn, Goodhue, Houston, Mower, Olmsted, Rice, Steele, Wabasha, Winona; District IV: Aitkin, Carlton, Cook, Lake, Pine, St. Louis; District V: Chippewa, Cottonwood, Jackson, Lac qui Parle, Lincoln, Lyon, Murray, Nobles, Pipestone, Redwood, Renville, Rock, Yellow Medicine; District VI: Anoka, Chisago, Dakota, Hennepin, Isanti, Kanabec, Ramsey, Washington, Wright; District VII: Becker, Big Stone, Clay, Douglas, Grant, Norman, Ottertail, Pope, Stevens, Swift, Traverse, Wilkin; District VIII: Benton, Crow Wing, Kandivohi, Meeker, Mille Lacs, Morrison, Sherburne, Stearns, Todd, Wadena.

Earlier figures have shown that a considerable number of physicians in all types of practice responded to the survey. Inevitably, general practitioners comprised the largest number of the total, 45.8 per cent, with "others" next, 28.2 per cent, internists and surgeons equally represented, 11.1 and 10.7 per cent, respectively, and pediatricians the smallest group, 4.0 per cent. These figures indicate the participation by physicians in the survey and result from the natural distribution of physicians in various types of practices. When the reported cases of active rheumatic fever are examined in terms of the various types of practice, however, quite different percentages are found. Again, the highest percentage of cases are reported from doctors in general practice, 75.0 per cent. Internists and pediatricians, both specialist types of practice, report equal percentage of cases, 11.2 and 10.5 per cent. Surgeons and others report only 2.0 and 1.0 per cent of cases, as might be expected.

Not all general practitioners, internists, and pediatricians, who returned questionnaires, report treating cases of active rheumatic fever during the past twelve months. This was more frequently true in replies from internists, 57.9 per cent reporting no cases, than in general practitioners, 35.4 per cent, and pediatricians, 27.5 per cent, of whom reported no cases.

When the replies to the second question are considered, some expected differences appear. This question asked for the number of patients under fifteen years of age treated for active rheumatic fever currently or during the past twelve months. The 1,519 physicians returning questionnaires reported a total of 1,434 cases of rheumatic fever in children under fifteen years of age. These cases were reported by only 478 (31.4 per cent) of the total physicians reporting, and represent an average of 3.0 cases for each case-reporting doctor.

Arranging these cases by type of practice of the reporting physician as in Table VII, it is apparent that the average number of cases occurring in children is greatest for pediatricians, with gen-

TABLE VII. REPORTED CASES OF ACTIVE RHEUMATIC FEVER UNDER 15 YEARS OF AGE, BY TYPE OF PRACTICE

Type of Practice	Questionnaires Returned	Positive Replies	No. of Cases	Average Per Reply	Per Cent of Total
Internist	173	27	48	1.7	3.3
Pediatrician	62	45	236	5.2	16.5
General	707	389	1112	2.8	77.5
Surgeon	166	11	26	2.3	1.8
Other	411	6	12	2.0	0.8
Total	1519	478	1434	3.0	99.9

eral practitioners reporting the next highest average. Also for these younger patients, the percentage of all the cases reported by pediatricians rises, and the percentage reported by internists drops considerably, as compared to the situation for rheumatic fever cases regardless of age. Again, however, the general practitioner group reports by far the greatest percentage of the total number of cases, 77.4 per cent.

In addition to the five counties not reporting any cases of rheumatic fever, three other counties, Clearwater, Lake, and Sherburne, reported no cases in children under fifteen years of age. Only one physician returned a questionnaire from one of these counties, and two replies were received from each of the other two counties.

The same comments regarding the distribution of cases by counties that were made earlier in relation to all reported cases hold true for the cases in children under fifteen years. It is true that pediatricians are relatively few and located in more metropolitan areas, but their data is likewise included in the Table VI showing rates per 1,000 population by districts.

Again it is difficult to explain why some physicians report treating cases while other physicians do not. Seventeen (27.5 per cent) of all the pediatricians returning questionnaries reported treating no cases of active rheumatic fever in children currently or within twelve months. Their colleagues who did report cases averaged 5.2 such cases in their practices. It would seem that if the disease occurs to that extent in the practice of forty-five (72.5 per cent) of all pediatricians, the remaining pediatricians should be seeing some cases. Further study of the negative replies may help to explain this.

The third question of the survey asked the doctor to report the number of individuals in his practice to whom he was currently giving some form of prophylaxis to prevent the development of rheumatic fever. The question was intended to give another indirect numerical measure of the size of the rheumatic fever problem in general, to supplement the data regarding active cases of the disease.

TABLE VIII. REPORTED NUMBER OF INDIVIDUALS RECEIVING PROPHYLAXIS AGAINST RHEUMATIC FEVER, BY TYPE OF PRACTICE

Type of Practice	Questionnaires Returned	No. of Positive Replies	Number of Individuals	Average	Per Cent of Total
Internist	173	95	433	4.5	13.0
Pediatrician	62	50	624	12.4	18.8
General	707	473	2183	4.6	65.6
Surgeon	166	14	55	3.9	1.6
Other	411	12	28	2.3	0.8
Total	1519	644	3323	5.1	99.8

Of the 1,519 physicians returning questionnaires, 644 (42.3 per cent) reported that they were giving prophylaxis to their patients. This is a slightly higher proportion of doctors than reported actual cases of the disease, indicating that physicians recognize the importance of prevention of the disease even when they are not seeing cases in their practice. The 644 physicians reported a total of 3,323 individuals who were being given some form of prophylaxis. This is an average of 5.1 persons for each reporting doctor. Compared to the total number of active cases of rheumatic fever reported, 2,297, an average of 1.4 individuals were receiving prophylaxis for every case reported.

When the data is arranged by type of practice of the reporting physician as in Table VIII, it becomes apparent that pediatricians as a group prescribe prophylaxis for almost three times the average number of individuals that other physicians do. Very little difference appears among internists, general practitioners, and surgeons.

Again, general practitioners reported the largest portion of all the individuals receiving prophylaxis, but internists and pediatricians reported an appreciable number, greater in terms of percentage than their share of all active cases of rheumatic fever reported in the survey. Doctors from eighty-five of the state's eighty-seven counties reported giving prophylaxis of some kind to individuals in their practices. One negative report was received from one county, Kanabec, where four physicians were queried, and one negative questionnaire was returned from the second county, Dodge, where seven physicians were queried.

Variations in the degree to which prophylaxis was reported from various counties is shown in Table IX, where counties are grouped into districts.

The significance of the data reported on the questionnaires is difficult to determine. It must be remembered that the questions called for a quick numercial answer that in many cases, no doubt, was solely an estimate. However, the average number of cases or individuals receiving prophylaxis reported in any doctor's practice was uniformly small, so that his estimate would seldom be very far off. More often, the doctor would know exactly how many such patients to report. Undoubtedly there may be some duplication of reporting, inasmuch as one patient may have visited more than one physician, but it is felt that this is not a major source of error. It should be remembered that only half of all the physicians who were sent questionnaires returned them. Because the participation by physicians, despite this response, was still fairly representative of all areas, types of practice, and type of response whether positive or negative, it may be argued that the reported numbers of cases and individuals receiving prophylaxis could be safely doubled on the basis of results reported.

TABLE IX. REPORTED NUMBER OF INDIVIDUALS RECEIVING PROPHYLAXIS, RATE PER 1,000 POPULATION, BY DISTRICTS

District	Headquarters	1954 Estimated Population	Number of Individuals	Rate Per 1,000 Population
I	Bemidji	227,164	135	0.59
II	Mankato	269,976	340	1.25
III	Rochester	329,853	417	1.26
IV	Duluth	285,438	185	0.64
V	Worthington	227,423	267	1.17
VI	Minneapolis	1,308,909	1501	1.14
VII	Fergus Falls	220,812	243	1.09
VIII	Little Falls	269,297	235	0.87
	Total	3,138,872	3323	1.05

Be that as it may, another serious question affecting the significance of the survey results lies in the nature of the disease which the doctor reported as a case of active rheumatic fever, or against which he was prescribing prophylaxis. Comments on a number of replies indicated that some physicians feel that the diagnoses of rheumatic fever made by their colleagues do not represent true instances of the disease, and that the term rheumatic fever is applied much too loosely to fairly large numbers of illnesses for want of a more exact diagnosis. It is hoped that additional study of a few representative counties, with more regard to the clinical disease entity reported by physicians, will help to clarify this situation. The present survey, by definition, aimed solely at assessing the rheumatic fever problem as defined by individual practicing physicians.

TABLE X. REPORTED CASES, PER 1,000 POPULATION, OF POLIOMYELITIS, RHEUMATIC FEVER, AND TUBERCULOSIS, MINNESOTA, SELECTED YEARS

Disease	Maximum Year, 1950-54		Minimum Year, 1950-54	
	Cases	Rate Per 1,000	Cases	Rate Per 1,000
Poliomyelitis: All ages	3926	1.28	502	.17
Under 15 years	2546	2.92	315	.38
Tuberculosis: All ages	2688	.90	1629	.52
Under 15 years	115	.14	82	.09
	Cases		Rate	
Rheumatic Fever: All ages	2290		.73 (1955 Survey)	
Under 15 years	1428		1.53 (1955 Survey)	

The reported incidence rates for active rheumatic fever may be compared with similar rates for other diseases, commonly recognized as problems. Table X shows these figures, from data of the Minnesota Department of Health. When the recurrent, long term nature of rheumatic fever, with its serious disabling complications, are recalled, these rates would indicate the real problem that the disease still poses.

Summary

Of 3,063 questionnaires on the current problem of rheumatic fever sent to physicians in Minnesota, 1,556 were returned. Five hundred and ninety-seven reported a total of 2,297 cases of active rheumatic fever, from eighty-two of the state's eighty-seven counties. Of the cases, 1,434 were under fifteen years of age. Six hundred and forty-four physicians reported that they were giving some form of prophylaxis to prevent the development of rheumatic fever to a total of 3,323 individuals..

These data, from 50.8 per cent of all physicians queried, indicate an incidence rate of rheumatic fever, of .73 cases per 1,000 population, all ages, or 1.5 to 1.7 per 1,000 population for children under age fifteen years. The data indicate also that at least 1.05 persons per 1,000 population are currently receiving some form of prophylactic therapy to prevent rheumatic fever.

Home Accident Prevention

A. B. ROSENFIELD, M.D., M.P.H.
Minneapolis, Minnesota

HOME accidents are causing a death every eighteen minutes and an injury every seven seconds in the United States. In Minnesota last year, one out of every fifty-two deaths was caused by a home accident. Fatal accidents are only part of the picture. According to the National Safety Council, for every fatal home accident there are four permanent disabilities and from 100 to 150 non-fatal accidents. This means that in addition to the 538 men, women and children who lost their lives as the result of home accidents in Minnesota in 1954, more than 2,000 were permanently disabled and about 70,000 suffered minor or more serious injuries.

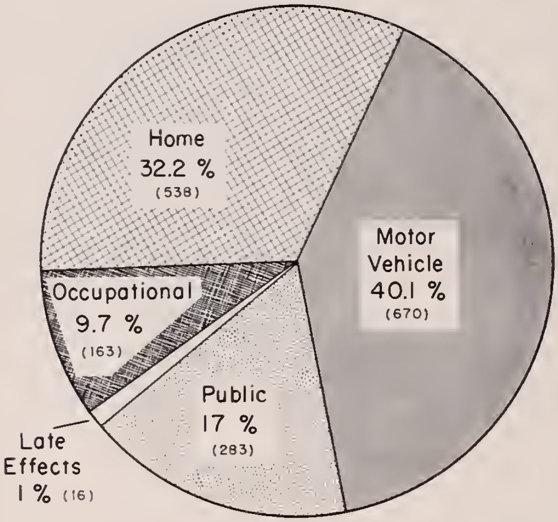

Fig. 1. Accidental deaths by major classification (1670 deaths) by occurrence in Minnesota, 1954. Minnesota Department of Health.

Now, just what is an accident? One dictionary defines an accident as an unexpected or unforeseen event, generally unfortunate. Many of the events that are tabulated as accidents would hardly qualify under this definition, except for the last phrase, "generally unfortunate." The National Safety Council states that an accident includes any suddenly occurring unintentional event which causes injury or property damage. A home accident is one that takes place within the home or on the home premises.

There was a total of 1,670 accidental deaths in Minnesota in 1954. Of these, 670 (40 per cent) were motor vehicle deaths; 538 (32 per cent) were home fatalities. Thus, home fatalities are almost as serious a problem as motor vehicle deaths, actually less than 8 per cent difference; yet traffic accidents steal the limelight because they are spectacular and home accidents receive comparatively little public attention (Fig. 1).

Falls account for the greatest number of fatal home accidents, 317 (60 per cent). Next, in order of frequency, were burns, responsible for 75 deaths; poisoning, 37; mechanical suffocation, 32; firearms, 13; drowning, 9; and machinery accidents, 8 deaths (Fig. 2).

Age is a significant factor in home accidents, with the extremes of life most frequently affected. Home accidents killed 308 people 65 years of age and older, and 77 persons from 45 to 64 years (Table I). They also took the lives of 82 children under five years of age, and 33 from 5 to 14 years. There were only 38 deaths between 15 and 44 years of age. Thus, more than half (57 per cent) of home fatalities involved those 65 years and older, and 71 per cent were 45 years of age and older. Twenty-one per cent were under the age of 15 years.

TABLE I. HOME ACCIDENT DEATHS BY SPECIFIC AGE GROUPS, MINNESOTA, 1954

Ages	All Ages	0-4 Years	5-14 Years	15-24 Years	25-44 Years	45-64 Years	65 and Over
Totals	538	82	33	6	32	77	308
Per cent	100.0	15.2	6.1	1.1	6.0	14.3	57.3

As to sex, under the age of nineteen, there are twice as many fatal accidents in boys as in girls. In old people this is reversed. In those sixty-five

---

Dr. Rosenfield is Chief, Section of Maternal and Child Health, Minnesota Department of Health.

Presented at Minnesota Public Health Conference, September 30, 1955, at Minneapolis, Minnesota.

years of age and older there are twice as many fatalities in women as in men.

The leading cause of death in childhood is not heart disease, cancer, or communicable disease. And certainly not poliomyelitis. Accidents are the leading cause in childhood, responsible for more than one-third of all deaths and equalling the total of the next four or five leading causes combined (Fig. 3). In 1954, accidents caused as many deaths as the total caused by cancer, pneumonia and influenza, diseases of the central nervous system, poliomyelitis, nephritis, rheumatic fever, measles, and tuberculosis.

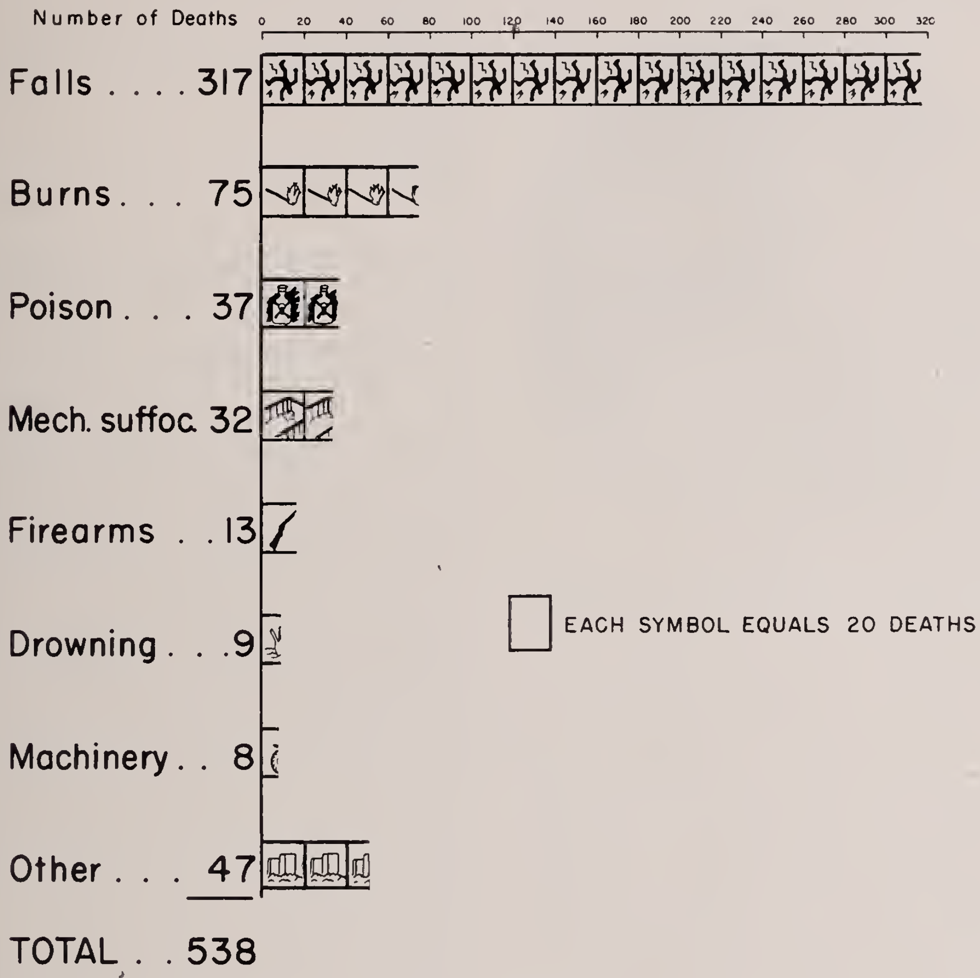

Fig. 2. Major causes of fatal home accidents by occurrence in Minnesota, 1954. Minnesota Department of Health.

While one-half of fatal child accidents are home fatalities the specific causes of child fatalities differ somewhat from the home accident summary, because motor vehicle and other public accidents are included (Table II). Of the 244 accidental deaths in children under the age of fifteen in 1954, eighty-two (33.6 per cent) were motor vehicle fatalities and forty-two (17.2 per cent) were drownings. Thus, motor vehicle fatalities are the leading cause of accidental deaths in childhood, responsible for one-third of such deaths. These include not only non-collision and collision of motor vehicles in which children are riding or driving but also motor vehicle-bicycle accidents as well as motor vehicle-pedestrian accidents. Motor vehicle-pedestrian accidents account for one-half of motor vehicle deaths in children. Of these three-fourths are under ten years of age, an age during which close parental supervision should prevent most of these fatalities. These involve children playing in the streets, darting behind cars into the street, chasing balls or toys into the path of automobiles, or crossing the street or road other than at intersections. These accidents also include fatalities in the driveway, garage, front of the home or in the back yard, frequently, because parents failed to "stop, look, and listen" before driving their car.

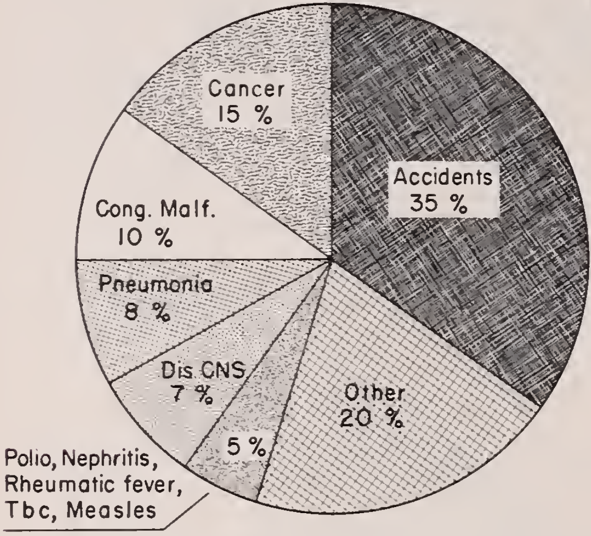

Fig. 3. Leading causes of death among children one to fifteen years by occurrence in Minnesota, 1954. Minnesota Department of Health.

Drownings are the second leading cause of accidental deaths in children, responsible for one-sixth of the deaths (17.2 per cent). These include public as well as home drownings. Drownings occur because babies are left in the bathtub while the mother answers the phone or doorbell; because young children are left near unfenced garden pools, near water troughs, open wells or cisterns on the farm; because children do not know how to swim, or swim alone or dive in unexplored water. Drownings occur because we disregard safe rules of boating, swimming and skating and because we do not know life saving measures.

In home accidents, falls are the leading cause of death (Table III). Falls took the lives of 302 persons forty-five years of age and older, almost 90 per cent of these being sixty-five years and over. Only fifteen fatal falls were recorded for persons under forty-five years of age, and eleven of these occurred in children under the age of fifteen. It is evident that falls are a particularly serious problem for those in the sixth decade of life and beyond where the physical infirmities of older age play an important role. While falls are frequent in children they cause few deaths in this age group.

TABLE II. PRINCIPAL CAUSES OF ACCIDENTAL DEATHS IN CHILDHOOD 0-14 YEARS, BY NUMBER AND PER CENT, MINNESOTA, 1954

Type of Accident	Number	Per Cent
Total	244	100.0
Motor Vehicle	82	33.6%
Drowning	42	17.2
Mechanical suffocation	30	12.3
Burns and conflagration	22	9.0
Obstruction or suffocation by food or external means	17	7.0
Falls	12	4.9
Machinery	10	4.1
Firearms	9	3.7
Poisoning	8	3.3
Other	12	4.9

Fatal falls result from accidents in all rooms of the home, on the stairs, as well as in the yard. They occur from tripping over a carpet, from stair carpeting and scatter rugs that are not tacked down or do not have non-skid rubber backing; from poor arrangement of furniture with foot stools, magazine racks, smoking stands and other small pieces of furniture placed where they can be tripped over. Falls occur from inadequate lighting, from lack of bedside lights and readily accessible light switches, and from lack of hand grips and bath mats for shower stalls and tubs. Fatal falls occur from use of makeshift ladders of boxes or chairs, from using stairs as storage areas, from leaving roller skates and other toys on the steps or floor. Falls also occur from leaving garden tools and other equipment lying about the yard and from slippery steps and walks. Prevention requires good housekeeping, periodic checkups and proper supervision of the infirm and aged.

Burns caused seventy-five deaths in 1954. Thirteen deaths occurred among children under the age of five, and twenty-two were sixty-five years or older. Thus, almost half occurred at the extremes of life. Fatal burns resulted from permitting babies and toddlers in the kitchen while meals were being prepared, or near containers of boiling water or hot grease, or having pot and pan handles on the stove where youngsters could reach them. Fatal burns resulted from failure to keep matches in metal containers out of reach of children, from faulty gas stoves or furnaces, chimneys and flue passages, and from untended trash burning or bonfires. Burns were also caused by careless smoking, especially in bed, and from the foolhardy practice

TABLE III. HOME ACCIDENT DEATHS BY CAUSE AND SPECIFIC AGE GROUPS
MINNESOTA, 1954

Type of Accident	All Ages	0-4 Years	5-14 Years	15-24 Years	25-44 Years	45-64 Years	65 and Over
Home Total	538	82	33	6	32	77	308
Falls	317	4	7	—	4	30	272
Fire, explosion, burns	75	13	7	3	15	15	22
Poisonings	37	7	1	1	7	17	4
(gas excepted)	(16)	(7)	(1)		(4)	(4)	
Mech. suffocation	32	30	—	1	—	1	—

Machinery	10	3	7	—	—	—	—
Other	54	25	5	—	4	12	8

of pouring gasoline or kerosene on fires to kindle or hasten them.

Accidentally swallowed poison resulted in seven deaths in children under age five, almost half of the sixteen poisonings of this type. Poisonings resulted from leaving medicines, poisons, and cleaning compounds as lye, ammonia or silver polish where children could reach them; from failure to read labels on medicine; from failure to clearly mark poisons and to keep them locked up; from taking medicine in the dark, and from failure to promptly take the proper antidote and to call a physician.

Poisoning from gas and vapors occurred mostly in adults and resulted in twenty-one deaths. They are most frequently the result of running the motor of a car in a closed garage, and occasionally from use of unvented gas heaters, or from gas escaping as a result of the flame being extinguished by boiling water on a gas stove.

There were more deaths from firearms in and around the home than from hunting accidents. Ten occurred as the result of hunting accidents; thirteen were home fatalities. Of the latter, six were between five and fifteen years of age. Accidents involving firearms are due to failure to unload guns, cleaning guns improperly, dropping or knocking them off a support, leaving guns where children can find them, and neglecting to keep guns and ammunition in separate places and locked up. These accidents happen because children and youth are not taught the dangers of firearms, and are not properly trained in the safe handling and use of firearms.

A few words should be said about mechanical suffocation in bed or cradle, listed as the cause of death in thirty children under the age of one in 1954. Many so-called cases of suffocation by bed clothes are actually the result of an acute respiratory infection, frequently virus in origin. While some of these deaths may be due to suffocation, many are due to unrecognized fulminating disease. Under such circumstances it is important that an adequate autopsy be carried out. Only by this means will it be possible to avoid that unfortunate "guilt complex" that parents may develop in the belief that carelessness was responsible for the death of their baby.

Home accidents are of particular concern to public health workers because: (1) they affect large numbers of people; (2) they affect every locality and every age group; (3) they are the leading cause of death in childhood; and (4) they are in seventh place among the ten leading causes of death in Minnesota. Home accidents have become one of our serious public health problems.

How individuals can best be made aware of the implications of safe homes, safe equipment and safe habits is still an unanswered question. The greatest obstacle to home accident prevention, according to the National Safety Council, is the fact that each householder must be his or her own "safety engineer." Unfortunately most householders are unaware that there are any serious hazards in the home or yard. It is important to note that accident prevention is not only a physical problem but is also a psychological problem. It must also be emphasized that accidents do not just happen; they are not acts of God. Accidents are caused. They are caused either by defects in the environment or by defects in human behavior, or more often by both. Therefore, there are practical methods for reducing the number and severity of home accidents.

Health workers must first be acquainted with the size and extent of the problem. They must know the number and type of fatalities and their relative importance in comparison with other causes of death. They must know the causes of home accidents, by type of accident and specific age group, and the specific preventive measures. They must, of course, know how to apply public health methods and techniques.

Public health workers should participate in the tabulation and analysis of records to determine the local problem by: (1) study of home accident death certificates, (2) follow-up of fatal home accidents through the family, the physician or the coroner, (3) study of non-fatal accidents in the community. They should help develop and promote the reporting of all accidents in the schools. They should promote the study of home accident cases in local hospitals through the local medical society and hospital staffs. They should participate in safety inspections. They should stimulate interest in the development and extension of local safety councils or other civic groups interested in home safety.

Finally, certain health workers and their possible contributions to the home safety program should be specifically mentioned.

The Physician.—The general practitioner has a vital role in attempting to reduce the toll from childhood accidents. He sees about 90 per cent of all children, while pediatricians see about 10 per cent. By pointing out to parents the physiology and development of the child and the anticipated changes, the physician can teach parents the necessity for child protection in early life from danger he cannot appreciate. Children under the age of one are entirely dependent upon some adult for their comfort, their care, their feeding, and their safety. He can point out the need for education and planned experiences in later childhood, within the limits of his developmental abilities, specific interests and local opportunities. And, when reason is not possible he can impress upon parents the necessity for discipline. With the aged, good medical care and adequate supervision are necessary and adjustments must be made for their years and needs.

The *public health nurse* is a key person in home safety because of her easy access to and acceptance in the home. She has the opportunity to observe the habits of the mother, the use of faulty equipment and poor housekeeping. She should observe potential accident hazards and should suggest corrections. She should incorporate home safety in her home visits by emphasizing safety in her teaching especially in maternal, infant, child, nutrition, care of the aged and in the administration of medications and treatments. Home safety should be included in her school activities as well as through teacher-parent-child and nurse conferences. She should interpret accident causes and prevention to community groups and should encourage community participation in home accident prevention activities. Perhaps it might be more effective to stress injury prevention activities.

Public Health engineers and sanitarians should include the investigation of potential hazards and safety education in their daily activities. Sanitation personnel can bring to the attention of the householder existing environmental hazards in the home or yard, unsafe activities, and the best means of controlling or eliminating such dangers.

Health educators can assist in the development and extension of home safety programs and can develop effective audio-visual aids as literature, films, slides, exhibits, as well as radio and television scripts and news releases to be used in such programs.

These techniques are the ones which health workers apply to other phases of preventive medicine: education, inspection, and the recognition and correction of physical, mental, emotional and environmental defects. These techniques should stimulate the family to develop safe habits and practices; they should promote community interest and participation in effective home safety activities; they should ultimately lead to a lowered incidence of home accidents.

ACHROMYCIN*

Tetracycline *Lederle*

in the treatment of

respiratory infections

January and his associates[1] have written on the use of tetracycline (ACHROMYCIN) to treat 118 patients having various infections, most of them respiratory, including acute pharyngitis and tonsillitis, otitis media, sinusitis, acute and chronic bronchitis, asthmatic bronchitis, bronchiectasis, bronchial pneumonia, and lobar pneumonia. Response was judged good or satisfactory in more than 84% of the total cases.

Each month there are more and more reports like this in the literature, documenting the great worth and versatility of ACHROMYCIN. This antibiotic is unsurpassed in range of effectiveness. It provides rapid penetration, prompt control. Side effects, if any, are usually negligible.

No matter what your field or specialty, ACHROMYCIN can be of service to you. For your convenience and the patient's comfort, Lederle offers a *full* line of dosage forms, including

ACHROMYCIN SF

ACHROMYCIN with STRESS FORMULA VITAMINS. Attacks the infection—defends the patient—hastens normal recovery. For severe or prolonged illness. Stress formula as suggested by the National Research Council. Offered in Capsules of 250 mg. and in an Oral Suspension, 125 mg. per 5 cc. teaspoonful.

For more rapid and complete absorption. Offered only by Lederle!

dry-filled sealed capsules

Hematoma of the Rectus Abdominis Muscle

JOHN EILER, M.D.
Park Rapids, Minnesota

NO DOUBT more cases of hematoma of the rectus abdominis muscle occur than are recognized, but the entity is rare enough to cause nterest when encountered. I have seen only two uch patients in nineteen years of general pracice.

Diagnosis

A hematoma of the rectus abdominis muscle may e mistaken for a number of intra-abdominal onditions. In only a small percentage of the ases is the diagnosis made preoperatively. This due to the rarity of the condition, as the diagnosis should not be mistaken if kept in mind. The diagnosis is not as simple, however, as seems bvious to the uninitiated. In addition to right ower quadrant pain, nausea and moderate eukocytosis complicate the picture.

Anatomy and Mechanics Involved

The rectus abdominis muscle undergoes great tress in carrying out the ordinary functions, as vell as the unusual ones, to which it falls heir. t must take part in such activities as coughing nd sneezing, defecation and regulating intrabdominal pressure.

The blood supply of the muscle is from the uperior and inferior epigastrics. They flow ephalad and caudad, respectively, in a groove n the dorsal surface of the rectus muscle for a hort distance before entering the substance of e muscle. This dorsal location of the vessels blood supply obviously was intended to prevent pture of the vessels and the consequent hemama formation. Incidentally, absence of the osterior rectus sheath, caudad from the linea micircularis of Douglas, is no doubt instrumental bringing about symptoms simulating intradominal pathology when thrombosis occurs, as nearly always does, near the distal end of the uscle.

Another salient feature of the anatomy of the tal end of the rectus muscle is that a hematoma ere not only can dissect laterally but may spread to the opposite side. In addition to peculiarities of the anatomy, there are such precipitating causes as coughing, child bearing, athletics, direct trauma, debilitating diseases and blood dyscrasias.

Report of a Case

A twelve-year-old white boy was brought to my office by his parents on July 23, 1954. The parents gave a history that "the boy ruptured himself a couple of days ago." Examination revealed no cough reflex in the inguinal canal, but he did display a rigid, tender mass just proximal to the symphysis pubis on the right side. He was nauseated and his white blood cell count was 9,000 per cubic mm. He was sent home with instructions to keep an ice bag over the mass continuously and to carry out strict bed rest. Menadione, gr. 5 three times daily was prescribed.

The parents reported back to my office every few days, assuring me that the patient was improving. However, they brought him to my office on July 28, 1954, at which time there was a large fluctuating mass at the site of the previous small rigid one. The skin over the area was deeply discolored. He was taken to the hospital for operative intervention.

The distal portion of the right rectus muscle was exposed by a paramedian incision down to and including the anterior rectus sheath. Most of the clot was easily evacuated, but some of it was intimately associated with the fibers of the muscle. Considerable active bleeding was encountered. The sources of this were sought out and the vessels ligated. A fairly dry field was obtained, and the incision was closed in layers without drainage. A pressure dressing was applied and an ice bag was kept over this for the first two postoperative days.

Microscopic section of the clots removed showed fibrocollagenous tissue with areas of fibroblastic proliferation and round cell infiltration. A few well formed capillaries were scattered through the tissue.

The patient's convalescence left much to be desired since the mass had returned to its preoperative size by the third day. Removing two sutures to provide drainage, and continuous boric acid solution packs turned the tide, however. He was discharged on August 9, 1954, with instructions to continue with the boric acid solution packs at home. It required about a month before his recovery was complete.

My second patient was that of a twenty-six-year-old veteran. He went to a veteran's hospital after my diagnosis, and I was unable to follow the course of his illness.

(Continued on Page, 222)

Pheochromocytoma in a Seven-year-old Girl

Report of Successful Removal

BERNARD J. SPENCER, M.D.
O. S. WYATT, M.D., an
TAGUE C. CHISHOLM, M.D
Minneapolis, Minnesot

A PHEOCHROMOCYTOMA is a functioning tumor of chromaffin tissue which usually arises in the adrenal medulla. Since chromaffin cells secrete epinephrine and nor-epinephrine, the tumors characteristically produce hypertension which may be paroxysmal or sustained.

Although the tumors are rare in children, they should be considered in the differential diagnosis of any hypertensive child because they represent a curable form of hypertension. Delay in diagnosis steadily increases the jeopardy of the patient.

This case is presented to illustrate the clinical course and surgical cure of one of the few patients reported during the first decade of life.

Case Report

History.—A seven-year-old girl was admitted to the hospital on April 14, 1953, with the chief complaints of severe headaches, irritability and episodes of nausea. The headaches began about a year prior to admission and occurred at irregular intervals. They were increasing in frequency and severity the past two months and were precipitated by any physical or emotional strain such as attending a birthday party or being teased by her brother. Her irritability had become so marked that despite sedation and analgesics, she had become unmanageable at home during the past week. She was anorexic, losing weight and had increasing bouts of nausea and vomiting. Drenching sweats were noted, despite her normal temperature.

Physical Examination.—The patient was thin and wore an anxious and distressed expression (Fig. 1a). She was 47 inches tall and weighed 37 pounds. Her temperature was 98.8° (rectal), pulse 130, respirations 24, and blood pressure upon admission was 194/150. The eye grounds showed a slight hyperemia of the right disc. No vascular spasm or papilledema was evident. There was a mild hypertrichosis of the face, trunk and extremities. Heart tones were loud with snapping systolic and diastolic sounds, but no murmurs were heard. Abdominal examination revealed no abnormality.

Laboratory Data.—The hemoglobin level was 14.6 gms., red blood count 4.77 million, leukocytes 10,650 with 67 per cent neutrophils, 31 per cent lymphocytes and 2 per cent monocytes. Urinalysis revealed 1+ albumin and 2-6 hyaline casts per low power field Determinations of blood urea nitrogen, basal metaboli rate and serum electrolytes were normal.

X-rays of the chest, skull and intravenous pyelogram revealed no abnormality.

An electrocardiogram showed a sinus arrhythmia an a tendency to right axis deviation.

Special Study.—Since the diagnosis of pheochromocytoma was suspected, a test using the adrenolytic agent benzodioxane, was done (Fig. 2). With the patien resting quietly blood pressure levels around 220/18 were first recorded. Following intravenous injection 10 mg. of benzodioxane the pressure fell within a minut to 120/60 where it remainded over five minutes.

Operation.—A polythene cannula was placed in th saphenous vein and 5 per cent glucose in water containing 4 cc. of Levarterenol (Levophed) per liter wa connected. A syringe of the depressor drug, phentolamine (regitine) was in readiness. A tranverse uppe abdominal incision was made. Gentle palpation reveale a tumor nearly 2 inches in diameter in the righ adrenal area. The remainder of the possible chromaffin tissue sites in the abdomen was examined includin visualization of the left adrenal which appeared normal The right adrenal tumor was then removed throug a transperitoneal approach. Despite the fact that th patient was receiving intravenous solution containin Levophed, she had a profound drop in blood pressur when the tumor was removed; and it was an hour late before she had stabilized well enough to be moved fro the operating table.

Pathologic Report.—The tumor measured 4 by 4 b 3 cm. and weighed 16 gm. (Fig. 3). The cut surfac had a pale tan color. Histologic sections showe pheochromocytoma.

Postoperative Course.—The patient did well until th second postoperative night when she experienced a ge eralized convulsion. She received intravenous sodiu amytal at intervals during the night and was n oriented for nearly twenty-four hours. The remaind of her convalescence, however, was most gratifying. H blood pressure remained stabile and she required r Levophed after the third post-operative day. The r duction in her pressure following surgery is shown i Figure 4. Her headaches, hyperhidrosis and nause ceased. The albuminura cleared within a week. H disposition and countenance reflected these improvements, and she was discharged on the twelfth postoperative day. Her improvement in the intervening two years may be noted in the recent photograph shown in Figure 1b. At her most recent office visit, a blood pressure of 100/62 was obtained.

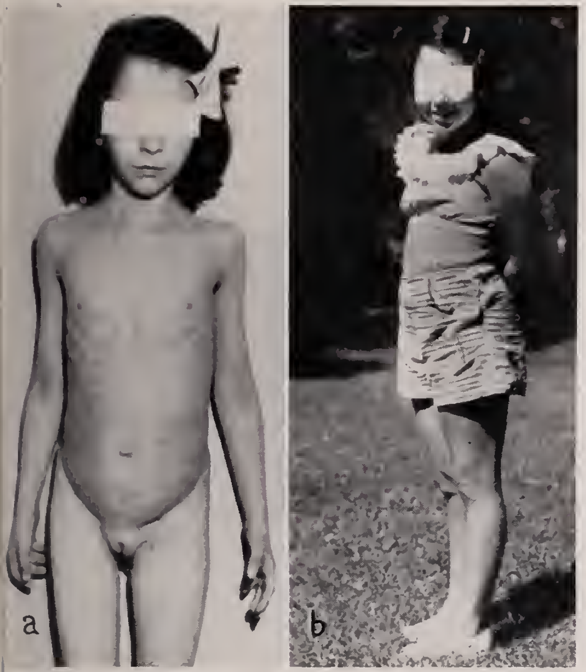

Fig. 1. Appearance of seven-year-old patient. (a) Preoperative. (b) Two years after operation.

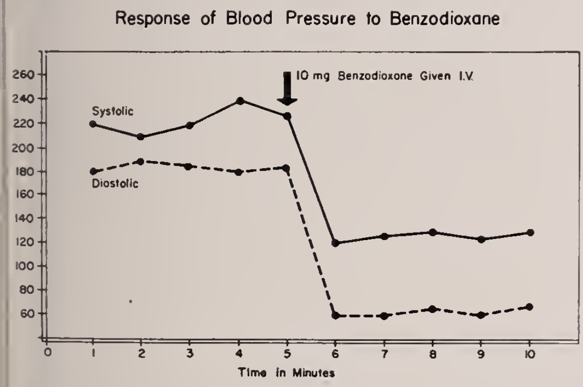

Fig. 2. Response of blood pressure to benzodioxane ijection.

Comment

The first adequate clinical description of hyper-ensive crisis in association with an adrenal tumor as given by L'abbe in 1922.[1] Charles Mayo reorted the first successful operative removal of ich a tumor with relief of symptoms in 1927.[2]

About three hundred patients have now been escribed in the literature who have been diagnosed in life or at autopsy. We were able to find reports on thirty-two children under the age of fourteen years.[3,4,5] The symptomatology parallels the adult cases in essential respects with anxiety and nervousness, hyperhidrosis and headaches the most common features in their histories. Of the thirty-two children reported, ten were diagnosed at autopsy, eight died at operation and fourteen survived surgical removal of the tumor.

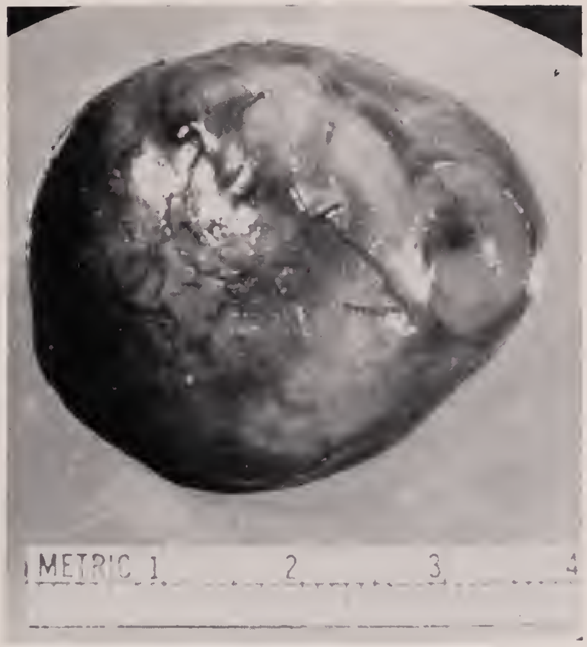

Fig. 3. Pheochromocytoma, gross appearance.

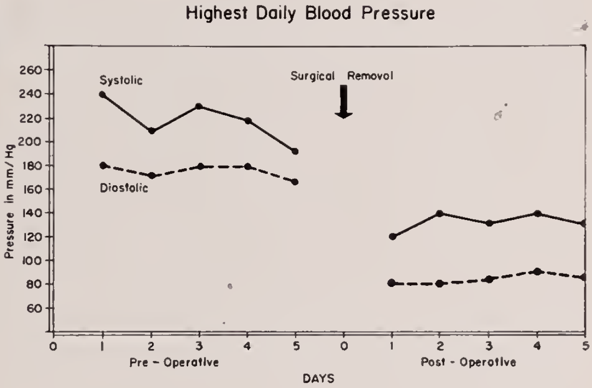

Fig. 4. Comparison of blood pressure, preoperative and postoperative levels.

The pharmacologic tests which are so valuable in diagnosis of pheochromocytoma have been developed during the past decade.[6,7,8] Two types of drugs may be used. Those which elevate the blood pressure are given to reproduce the patients' attacks, and those which act as adrenolytic agents are given to obtain an abrupt lowering of the hypertension when due to a tumor. It is the opinion of Kvale, Priestly, and Roth,[9] who have reported the largest series of these tumors, that histamine is the most reliable drug for diagnosing pheochromocytoma that causes paroxysmal hypertension, and phentolamine (regitine) and benzodioxane (benodaine) are the most valuable diagnostic agents in pheochromocytoma with sustained hypertension.[9]

Once the diagnosis is made, the treatment is surgical removal. Although the tumor may arise in any area where chromaffin tissue is present, nearly 90 per cent of the hypertensive cases occur in the adrenal medulla. About one-fifth of such cases are bilateral or multiple.[10] Because of the high incidence of bilateral tumors, elaborate diagnostic attempts to localize an adrenal tumor have little to commend them. A transverse upper abdominal incision allows the best access to the potential tumor sites. The tumor should be manipulated or compressed as little as possible; the adrenolytic agent, regitine, should be used to combat blood pressure elevation; hypotension following removal of the tumor must be corrected with the use of the pressor drug, Levophed. Postoperatively the systolic pressure should be maintained over 100 mm. by regulating the rate of flow of a constant intravenous solution of 5 per cent glucose in water containing this drug. The patient may require Levophed in such a manner for several days. It is interesting to note that the severity of the clinical symptoms may have no correlation with the size of the tumor.

Summary

This report presents the clinical course an management of a seven-year-old girl with a adrenal pheochromocytoma. Following operativ removal of the tumor, her symptoms and hypertension have been relieved.

We wish to thank Dr. Robert Wilder and his associat for their valuable aid and co-operation in the management of this patient.

HEMATOMA OF THE RECTUS ABDOMINIS MUSCLE

(Continued from Page 219)

Treatment

This condition has been successfully treated both by conservative measures such as ice bags, bed rest and sedatives and by operative means. My patient received both. If operation is resorted to, the shorter the delay the better the results.

Summary

Attention is called to the rarity of hematoma o the abdominis rectus muscle. The anatom mechanics and functions of the parts involve are reviewed. A case is presented along with i treatment.

GROWTH HORMONE

B. J. KENNEDY, M.D.
Minneapolis, Minnesota

THE phenomenon of growth is dependent upon a multitude of interlacing factors, among hich hormonal regulation plays an important ole. Two phases of growth under hormonal conrol appear in the human subject. The first phase. repubertal growth, is largely under the regulaion of the pituitary growth hormone and has its ost rapid spurt during the first few months of fe with a gradual decrease in rate until puberty. rowth hormone has no effect on epiphyseal usion.

The second phase of growth begins at the onset f puberty and is attributed to the steroid horones derived from the gonads and adrenal ortex. In response to production of pituitary onadotropic hormones, the male and female onads, as well as the adrenal cortex, produce eroids that stimulate growth of bone and soft ssues. This stimulation results in skeletal maturaon and eventual closure of the epiphyses.

The serum inorganic phosphorus is elevated in e prepubertal age and appears to be an index f growth hormone production or activity. A fall inorganic phosphorus occurs during puberty. his decrease is probably the result of inhibition f pituitary growth hormone production by the eroid hormones.

Deviations from the normal growth pattern ccur when there is a decrease in or excessive roduction of pituitary growth hormone. Lack of fficient growth hormone results in the syndrome pituitary dwarfism. The decreased production ay result from pituitary hypoplasia or pituitary struction. In the majority of cases there is ually an associated hypogonadism as the result the lack of pituitary gonadotropin production.

Excessive production of pituitary growth hormone as the result of tumor or hyperplasia of the eosinophilic cells of the anterior pituitary results in the syndromes of gigantism or acromegaly. In gigantism excessive production of growth hormone occurs prior to the closure of the epiphyses and coincides with the normal prepubertal growth period. There is a proportional type of growth; abdominal viscera are large but not out of proportion to the rest of the skeleton. In acromegaly the overproduction of growth hormone occurs after epiphyseal closure. There is increased thickness of the entire skeleton and increase in total mass of soft tissues as well, without an increase in linear growth. The paranasal sinuses become enlarged and all cartilages calcify.

The serum inorganic phosphorus is elevated in almost all active acromegalic patients. The serum phosphorus can be depressed when either androgen or estrogen is administered and remains at lower or normal levels so long as steroid hormone is administered. This depression of serum phosphorus is usually associated with evidence of clinical improvement of the acromegalic state.[1] It appears that serum phosphorus is an index of pituitary growth hormone production; and androgenic and estrogenic hormones inhibit the production of pituitary growth hormone by the anterior pituitary and/or inhibit the peripheral effects of pituitary growth hormone.

The growth promoting properties of anterior pituitary extracts have been demonstrated for thirty-five years. More recently chemical procedures have been developed for obtaining crystallized growth hormone of varying degrees of purity which have been employed in biological investigations. Though a mass of literature has accumulated on the effects of growth hormone in animals, the data regarding human subjects is meager and contradictory. Extensive studies in animals have revealed not only the growth pro-

TABLE I. METABOLIC EFFECTS OF GROWTH HORMONE IN ANIMALS

1. Promotion of growth of skeleton and soft tissues.
*2. Increased nitrogen retention.
*3. Increased calcium retention.
*4. Increased phosphorus retention.
5. Elevation of serum inorganic phosphorus.
6. Elevation of serum alkaline phosphatase.
*7. Glycosuria.
*8. Impaired glucose tolerance.
*9. Increased insulin resistance.
10. Decrease in blood amino acids.
11. Increase in fasting ketone bodies.
12. Fat mobilization and decrease in body fat.
13. Increase of various enzymatic reactions.
14. Increase of glomerular filtration rate and renal plasma flow.
15. Galactopoietic effect.
16. Maintenance of muscle glycogen in hypophysectomized rats.
*17. Increase in rate of tumor growth of breast and prostate cancer (in man only).

*Effects demonstrated in man.

moting properties of this hormone, but its influence on a wide variety of metabolic processes[2] (Table I). Among these are an elevation of serum inorganic phosphorus and alkaline phosphatase, and increased retention of calcium, phosphorus and nitrogen. Convincing evidence is available that growth hormone increases the anabolism and decreases the catabolism of protein. The fundamental mechanism by which the hormone promotes the formation of body protein and spares protein stores during fasting is unknown.

An anti-insulin effect on carbohydrate metabolism has been demonstrated. This resulted in reversible or permanent glycosuria, reversible or permanently impaired glucose tolerance, and increased insulin resistance. The mechanism of this action is unknown. There appears to be an antagonism between insulin and growth hormone, possibly exerted on the enzyme hexokinase in the process of glucose phosphorylation. Whether growth hormone and diabetogenic hormone are the same or separate factors has not been clearly defined.

If the primary action of growth hormone is to decrease protein catabolism, more fat would be mobilized and utilized as an energy source. The hormone is capable of mobilizing body fat, produces ketonemia in fasting rats and decreases the total body fat. It appears unnecessary to postulate the existence of a specific ketogenic hormone in view of these effects on fat metabolism.[3]

Other metabolic effects consist of a decrease in blood amino acids, maintenance of muscle glycogen in hypophysectomized rats, increase in glomerular filtration rate and renal plasma flow, and enhancement of various enzymatic reactions. Little evidence has been gained, however, indicating the mechanisms by which these effects are produced.

The role of growth hormone in mamma development has been described.[4] In hypoph sectomized, oophorectomized virgin rats, mamma development simulating early pregnancy was i duced by injecting estrone, progesterone an lactogenic hormone. When growth hormone w injected, as well as these other hormones, comple lobulo-alveolar development similar to late pre nancy was induced. Lactation would occur ACTH or cortisone were also administered. I cows the administration of growth hormone caus significant increases in milk yield (galactopoiet effect).[5] The effect of growth hormone in man mary gland physiology appears well established.

The evidence for the action of administer growth hormone or somatotropin in man is scan The available data are contradictory as to wheth growth hormone can achieve protein anabol effects or influence carbohydrate metabolism, well as to reproduce metabolic processes describ in animals. The conflicting data is primarily t result of the lack of an adequately prepared pu preparation of growth hormone in sufficie amounts for clinical investigation. The di crepancies in data appear to be due to contamin tion of the hormone with thyrotropin or ACT loss of activity in handling the preparation, other problems related to its chemical preparatio The responsiveness to the hormone might also conditioned by the metabolic status of the subje treated. More recently the development of a anti-growth hormone factor has been postulate as an explanation for the lack of consistent i vestigations.[6]

Extensive metabolic studies have been carrie out in the human.[7-9] From these investigations is possible to draw some conclusions as to t action of somatotropin in human subject Crystalline somatotropin is capable of bringi about many of the major metabolic effec characteristic of this hormone in animals. The is enhancement of the storage of nitrogen, calciu and phosphorus requisite for the growth skeleton and soft tissues. Impairment in carb hydrate metabolism has been manifested by t development of a diabetic type of gluco tolerance curve, increased insulin resistance an glycosuria. All of these alterations were reversib No consistent changes have been observed in t serum inorganic phosphorus or alkaline phosph tase. Though an increase in height and weig of human subjects of short stature has occurr uring administration of growth hormone, the ata is too meager to permit any conclusions as o the efficacy of growth hormone in the therapy f pituitary dwarfism or children of short stature.

The pituitary gland is increasingly important n the control of the growth rate of certain alignancies. The improvements in advanced reast and prostate cancer as the result of the dministration of estrogens and androgens have een postulated to be the result of pituitary gland ppression, or a "chemical hypophysectomy." The dministration of growth hormone to a woman ith breast cancer previously hypophysectomized nduced osteolysis as measured by an increase in rinary calcium excretion.[10] This osteolysis is terpreted as due to an increased rate of tumor rowth. Growth hormone administered to a atient with metastatic prostate cancer resulted increased pain, increase in serum acid phoshatase, and increase in urinary calcium excretion Table II). Cessation of therapy was followed y a reversal of these changes. It was to be pected that total surgical hypophysectomy would employed in the management of advanced ncer of the breast and prostate. Numerous reorts to date[11,12] demonstrate that in selected atients striking regressions of metastatic tumors ave occurred as a result of surgical hypophectomy. The improvements noted are in part e result of deprivation of growth hormone.

The procedure of surgical hypophysectomy has so been employed in an attempt to control vere diabetes mellitus and forestall the development of secondary complications of this disease. view of the role of growth hormone in carbodrate metabolism, it is not unexpected to find decrease in insulin requirements and a decrease hyperglycemia and glycosuria following hypophectomy. The early investigative experience in is disease suggests that improvement in some lvanced vascular lesions can also be expected. hese studies demonstrate that the regulation of abetes mellitus by insulin and diet are not the ly factors involved in the control of this disease. rther research is being directed toward the tuitary factors.

Summary

Growth hormone affects fundamental metabolic ocesses of protein, carbohydrates, fats, minerals d various enzyme systems. With the development of purer hormonal preparations, the role of growth hormone in malignant diseases, diabetes mellitus and normal growth can be more clearly elucidated.

DIFFERENTIAL DIAGNOSIS OF LYMPHOCYTOSIS AND LEUKEMIA

R. DOROTHY SUNDBERG, Ph.D., M.
Minneapolis, Minneso

Lymphocytosis

Lymphocytosis occurs in a wide variety of conditions. Differential diagnosis ultimately depends upon qualitative changes in lymphocytes, but knowledge of the scope of the diagnostic possibilities is useful. Briefly, the following principles can be defined.

Infants from two weeks to two years of age generally show a normal "lymphocytosis," and they may respond to infections with minimal lymphocytosis rather than neutrophilia. A source of concern is the fact that their large lymphocytes may contain visible nucleoli. These are not of diagnostic importance.

Viral and other diseases associated with a tendency toward leukopenia often show a relative lymphocytosis. Lymphocytes may show leukotoid alterations comparable to those of infectious mononucleosis. This fact makes it difficult to diagnose with security the leukopenic phase of infectious monoucleosis.

In infants and young children, extremely high lymphocyte counts occur in two conditions other than leukemia. One, namely, infectious lymphocytosis, is characterized by a monotonous increase in the number of mature small lymphocytes. The lymphocytosis persists from three to seven weeks; as the percentage of lymphocytes decreases, the percentage of eosinophils increases. Rarely, the predominant lymphocyte is a medium-sized cell. The bone marrow may show a similar lymphocytosis, with 40 to 45 per cent lymphocytes. The second condition, namely, pertussis, shows a lymphocytosis comprised of cells that are more variable in size and morphologic structure. A few lymphocytes show leukocytoid alterations and a few may be immature, but most are norm lymphocytes, and the variability in the morph logic aspects of the cells does not approach th of infectious mononucleosis. When the tot leukocyte count is less than 65,000 cells per cub millimeter, infectious mononucleosis becomes i portant in differential diagnosis.

Leukemia

General findings in lymphatic leukemia a simpler to delineate than are those in benig lymphocytosis.

Chronic lymphatic leukemia, a disease adults, is characterized by a monotonous increa in mature lymphocytes of similar size and stru ture. Total counts vary from the normal range more than 1,000,000, with very high percentag of lymphocytes, but symptoms and signs need n vary accordingly. Immature lymphocytes are n prominent, but many smudged or damage lymphocytes are found in either blood or bo marrow. Lymphoblasts are almost never seen. Th cells resembling blasts are reticular lymphocyt comparable to those of infectious mononucleosis benign hyperplastic nodes. Biopsy of the bo marrow is helpful in diagnosis. Here, too, th monotonous picture of lymphocytosis exist lymphocytes vary from 20 to 90 per cent, wit an average of 60 per cent. If the relative an absolute numbers of lymphocytes are low in bot blood and marrow, sections of the aspirate marrow often are needed to establish the diagnosi

The various forms of subacute and acut lymphatic leukemia offer the most confusion b cause they are common in infants, children, an young adults, the same age range in which i fectious mononucleosis also is most common. anemia and thrombocytopenia have not yet beco profound, the clinical findings in these leukemi may mimic those of infectious mononucleosis. Th extreme malaise, the hyperpyrexia, and the natu

This is the thirty-seventh in a series of editorial reports sponsored by the Minnesota Society of Clinical Pathologists and designed to foster closer relationships between laboratory physicians and their colleagues.

f the pharyngitis in infectious mononucleosis ften make the patient who has infectious mononucleosis seem a much more likely candidate for mminent death than the patient with acute eukemia. Total leukocyte counts in subacute or cute lymphatic leukemia vary from leukopenic evels to considerably more than 200,000. Cells f the lymphocytic series dominate the differential ount. The general appearance of these cells is nonotonous insofar as similarity in size is con- erned. Lymphoblasts, immature lymphocytes nd mature lymphocytes are present. Acute ukemias have 60 per cent or more lymphoblasts; ubacute leukemias have less than 60 per cent mphoblasts. The lymphoblast is the cell that is ssential to the diagnosis of acute and subacute mphatic leukemia. It is abnormal in the eripheral blood and lymph nodes; it is not resent in benign lymphocytoses. The immature mphocyte, a cell that resembles the lymphoblast n size and paucity of cytoplasm but that rdinarily lacks nucleoli, occurs in large numbers n the acute and subacute lymphatic leukemias; is also found in normal lymph nodes and bone narrow and, occasionally, in normal blood as ell as in lymphocytoses. The similarity of the nmature lymphocyte to the lymphoblast is sponsible for much confusion in differential iagnosis. The bone marrow in either acute or ıbacute lymphatic leukemia contains high per- entages of lymphoblasts, immature lymphocytes nd mature lymphocytes, the average being 95 er cent. Study of bone marrow is particularly seful in diagnosis in the cases with normal or ukopenic peripheral leukocyte counts.

nfectious Mononucleosis—Lymphatic Reaction

The lymphocytosis of infectious mononucleosis robably remains confusing because no two cases e alike. The combination of the clinical findings d numerous lymphocytes with large amounts of ue cytoplasm and nuclei that occasionally have sible nucleoli is often alarming. Several features serve emphasis. Anemia and thrombocytopenia e generally absent. The leukocyte count may ry from 2,000 to 65,000 but the usual values e between 8,000 and 25,000. Percentages of mphocytes range from 25 to 85, but diagnosis difficult if the percentage is less than 50. Of utmost importance is the variation in size and structure; there is no monotony in the lymphocytic picture. Often the largest and bluest cells in the blood film contain nucleoli and resemble some blast form. These, the reticular lymphocytes (type III, Downey), are normal precursors of lymphocytes. They generally comprise only a small percentage of the lymphocytes. The majority of the lymphocytes show leukocytoid changes. Downey's type II or type I leukocytoid lymphocytes or both are present, and otherwise normal-appearing lymphocytes may have excessive azurophilic granulation or cytoplasmic basophilia. Occasional plasma cells are also seen. Because the fragile cytoplasm of the type II lymphocytes is often distorted, these cells may assume polygonal shapes. Often there is an absolute as well as a relative neutropenia, and occasional neutrophilic promyelocytes and myelocytes are found. Bone-marrow biopsy is not necessary for diagnostic purposes in most cases. Percentages of lymphocytes in the marrow range from 12 to 43, with an average of 25; about half of the lymphocytes in the marrow show leukocytoid changes, and evidence of formation of these cells in the marrow is present. About 40 per cent of the sections of aspirated marrow in infectious mononucleosis show small granulomatous lesions as well as foci of developing lymphocytes.

When high percentages of lymphocytes show leukocytoid changes, the condition is called a "lymphatic reaction." The changes in individual lymphocytes are comparable to toxic changes in neutrophils, and also they generally indicate stimulation of lymphatic tissue. Unless the lymphatic reaction is of considerable magnitude, its diagnostic importance is questionable. Lymphatic reactions can occur in infectious mononucleosis, brucellosis, infectious hepatitis, German measles, serum sickness, sepsis, viral diseases and agranulocytosis, and with eosinophilia. Plasma cells may also be present in any of these conditions. High percentages of plasma cells are seen in German measles, hepatitis and serum sickness. A blood picture indistinguishable from that of infectious mononucleosis is seen in very occasional cases of brucellosis and infectious hepatitis, so it should be remembered that morphologic studies alone will not exclude the latter conditions.

Current Concepts

THE PRESENT STATUS OF THE TREATMENT OF VARICOSE VEINS

DAVITT A. FELDER, M.D
Saint Paul, Minnesot

The existence of different types of treatment for a disease makes it seem likely that none is completely satisfactory. This appears to be true of varicosis of the veins of the lower extremities.

There has been some progress made in the past few years, both in an improved understanding of the etiology as well as in the treatment of superficial varicosis of the lower extremities. Aside from inherent structural weakness, degeneration with age or trauma secondary to over-distention (as a result of deep vein obstruction) and hormonal changes, there is an increasing interest of late in the rôle of arteriovenous connections as an abetting factor in the development of varicoses. It is reasonable to assume that elements of more than one etiological factor may be responsible and at times in the same patient.

In a dilated vein, the valves cannot function efficiently. Approximation of the vein walls to one another by pressure from without is the basis for restoration of valve function and resolution and control of signs and symptoms. Elastic bandages or stockings are therefore still acceptable and popular forms of treatment. When the valve structures are destroyed or for some reason treatment with elastic support alone is unsuccessful, then functional or anatomical elimination of the incompetent and inefficient veins is indicated.

At the present time, ligation and intraluminal stripping are the most popular methods of treatment. The results are gratifying, especially in regard to the removal of some large superficial saphenous veins.

There is no doubt that by this technique one removes some of the diseased veins. On the other hand, there seem to be at least two misconceptions associated with this form of treatment. One is that the connections with the perforating or communicating veins are disrupted. This is anatomically unlikely in most instances. The superficial veins often connect with the perforating or communicating veins by numerous and devious channels. The direct connections so often shown i simplified diagrams between the saphenous itsel and the deep veins are actually infrequent. Another is that stripping gives an outstandingly bette end result as far as future varices is concerned. I this author's opinion, it still remains to be prove that the results of stripping are appreciably bette in all or even most instances than with adequat high and serial ligations. The enlarged long o short saphenous veins often become indiscernibl within eight months after high ligation. It is tru that the extremely tortuous, dilated varicositie will tend to persist after high ligation alone. Bu these are also the varicosities that are almost impossible to strip out.

There is no comparison between the morbidit of simple and serial ligations to that followin stripping. It would not be surprising to see th procedure of vein stripping gradually lose popularity in favor of a return to simple high and seria ligations. With an adequate high ligation at th sapheno-femoral junction, the results after eigh months, in this author's series, are very gratifyin and appear to be comparable to those in patient with vein stripping.

The procedure of high ligation with retrograd injection, previously and still championed by McPheeters,[1] is now infrequently done. As shown b Wright, et al,[2] the sclerosing agent goes almost entirely into the deep veins. Here it can and probably does cause an appreciable amount of damag to valves and endothelium.

Abraham[3] has recently described the method o high ligation and the insertion of a silk suture int the distal vein to obliterate it. We have evaluate his technique, using both silk and catgut, and hav found it to have about the same postoperativ morbidity as vein stripping.[4] However, the actua rauma and blood loss were much less than with he stripping technique. It has another advantage that it can be done under local anesthesia.

Superficial varices remaining eight months after ny of the above procedures are best obliterated y the airfoam injection technique described by Ieyers of the Mayo Clinic.[5] A small amount of lerosing solution (we use 3 per cent sodium sotra- ecal*) is mixed with about three times as much r to make a foam. This foam is injected into the in with the patient in the reclining position. The r foam gives a great deal of endothelial contact ithout the presence of much blood. This leads to sclerosis without a large thrombus and thus a ner and incidentally less painful end result.

The surgical treatment of varices during preg- ncy can be accomplished without any greater orbidity than in nonpregnant individuals.[6] There some risk nonetheless. The fact that such veins turn to normal in most individuals within eight onths after parturition, makes surgical treatment nnecessary in such instances. With succeeding egnancies, the unresolved disease tends to in- ease. When such disease is symptomatic after ght months postpartum, then we believe surgery indicated. Occasionally the discomfort is so great d the nature of the vessels an actual hazard, that such instances surgical treatment during preg- ncy is indicated.

The hormone treatment of symptomatic vari- sis in pregnancy, as proposed originally by Mc- sland,[7] has not gained widespread popularity. owever, other authors have reported good results th this method[8] and McPheeters is still using it.

For the most part, conservative treatment, in- ding elevation of the foot of the bed, good stic support when up, avoidance of prolonged ting and prolonged standing and daily walks are is author's method of choice for the treatment the varicosities of pregnancy.

Ligation of the superficial femoral vein, as commended originally by Buxton, et al,[9] while ll done for the stasis syndrome is not very popu- . In the individual whose activities do not de- nd rapid or persistent walking, deep vein liga- n may still have a place and can be expected give some relief.

Popliteal vein ligation, popularized by Bauer[10] s fallen by the wayside. It is interesting that my league. Dr. Thomas O. Murphy, in thirty-two phlebographic studies on patients who had had popliteal vein ligations for the stasis syndrome found a popliteal vein of appreciable size visualized in all.[11] Either these patients had only one of two popliteal veins ligated or else a smaller collateral became dilated as a result of the popliteal occlusion. Most of the patients in our clinics who have had popliteal vein ligations for the stasis syndrome have returned with their old symptoms within one year.

The recent advances in phlebographic methods[12,13] have brought with them the documentation of varicosis of the deep and communicating veins in limbs presenting the stasis syndrome. They have also established the fact that in the postphlebitic limb the deep veins are usually patent although incompetent. This makes treatment by ligation, removal or obliteration of incompetent superficial veins a reasonable procedure in such limbs, whereas it was formerly thought to be an extremely hazardous undertaking.

These phlebographic studies have also brought out other possible etiological factors in the production of the stasis effect in the lower extremities. These techniques have resulted, in our experience, in a better control of surgical procedures for the ligation of communicating or perforating veins.[14] One can hope that these and improved methods of visualization of the deep veins will lead to further and better methods of treatment of the disorders of the veins of the lower extremities.

CASE PRESENTATION

WYMAN JACOBSON, M.I
and RALPH SMITH, M.I

Minneapolis, Minneso

A FORTY-ONE-YEAR-OLD clerk was admitted April 1 complaining of epigastric pain for one month. For nine years he had suffered from periodic episodes of epigastric distress, usually in the spring and in the fall. He had been examined roentgenographically on several occasions and told that there was no evidence of peptic ulcer and that he had a "nervous stomach." He had experienced no severe distress until the past month, during which time he had sharp pain across the epigastrium. The pain did not radiate; it was severe and frequently awakened him at night. Gelusil and milk accorded much relief. He vomited occasionally, which seemed to relieve him. He had noted no hematemesis nor celena. He had lost about 15 pounds in weight.

He had used alcoholic beverages freely for a few years but very little in the past eleven years. He had been treated for syphilis twelve years ago and was retreated several years later.

He was well developed, thin and in no acute distress. The temperature was 99.4° F., the pulse rate 82, the blood pressure 124 mm. of Hg systolic and 82 diastolic. The heart and lungs were normal to percussion and auscultation. There was slight epigastric tenderness and a succussion splash was heard over the stomach.

The hemoglobin was 13.5 gm. per 100 cc., the leukocyte count 15,700 (73 per cent neutrophils, 23 per cent lymphocytes, 2 per cent monocytes, 1 per cent eosinophils, 1 per cent basophils), the sedimentation rate was 50 mm. in one hour. The blood urea nitrogen was 13.5 mg. per 100 cc., the chlorides 92.7 mEq./1., Co_2 30.2 mEq./1., and potassium 4.5 mEq/1. Total serum protein was 6.8 gm. per 100 cc. (albumin 5, globulin 1.8). The urine specific gravity was 1.028, negative for albumin, faint trace of sugar, sediment contained 1 to 2 leukocytes per high power field. Fasting blood sugar was 91 mg. per 100 cc. The stool was negative for occult blood. The VDRL slide test was negative. Gastric analysis showed 52 units of free acid, 78 units of total acid. The serum amylase was 80 units. The serum bilirubin was 0.2 mg. per 100 cc. at one minute, the total being 1.0 mg. per 100 cc. There was 1.8 per cent retention of bromsulphalein at forty-five minutes, prothrombin was 84 per cent, cephalin flocculation negative, thymol turbidity 6 units.

A PA film of the chest was normal. An upper gastrointestinal series revealed a large penetrating ulcer of the antrum or of the first portion of the duodenum with obstruction to the outflow of barium.

He improved on continuous gastric suction and parenteral alimentation. However, he was unable to tolerate an ulcer No. 1 regime on several occasions when he had repeated vomiting and bedtime gastric aspirat measured 1500 cc. On April 8 a transfusion was di continued because of a generalized erythematous erup tion. Plasma hemoglobin and blood culture we negative. On April 12 he received 500 cc. of who blood when only slight urticaria was noted.

At operation on April 13 there was a large duoden ulcer penetrating into the head of the pancreas. A gastr resection was done with a Billroth II type of reconstru tion leaving the ulcer bed *in situ*. Procaine penicilli 300,000 units daily was administered, and dihydr streptomycin 500 mg. every six hours was begun. H condition that day remained satisfactory.

The following morning his rectal temperature w 103.5°, pulse rate 96 and blood pressure 70/30 mm. Hg. The hemoglobin was 15.9 gm. per 100 cc., th serum analyase was 135 units. The blood pressur stabilized at 120/78 after administration of 600 cc. plasma and 500 cc. of whole blood. The temperatur remained elevated, and that evening his blood pressur fell to 65/40 mm. of Hg. Intravenous administratio of vasoxyl was instituted and the blood pressure range about 102/56 mm. of Hg. An indwelling catheter wa introduced because of retention. Urine output wa satisfactory.

The second day following surgery his rectal tempera ture ranged from 103.5° to 106° F. Administration vasoxyl was continued and the blood pressure range between 70/50 and 110/60 mm. of Hg. The abdome was soft, there was no unusual tenderness, few bow sounds were heard. Urine output was adequate. Th hemoglobin was 14.7 gm. for 100 cc., the leukocyt count 4,700 per cu. mm. with 72 per cent neutrophil and 28 per cent lymphocytes. The serum amylase wa 60 units. Multiple films of the chest were negative Flat and lateral decubitus film of the abdomen showe gas in the large and small bowel and some mottlin over the upper quadrant. He received 300 cc. o plasma. Intravenous administration of terramycin 25 mg. every six hours was added to his therapeutic pro gram. His urinary output remained adequate. Th urine specific gravity was 1.023, albumin 3+, a trac of sugar, the sediment contained a full field of leuko cytes and 70 to 75 erythrocytes per high power field.

On the third postoperative day his condition was un altered. There was some swelling about the lips and generalized erythematous eruption with urticarial wheal which improved upon administration of Benadryl. H received 500 cc. of plasma. The rectal temperature wa 105° F. Levophed was now employed and the bloo pressure ranged from 80/70 to 100/70. He had a larg watery stool which did not appear to contain bloo On this day a second operation was performed.

Discussion

Dr. W. E. Jacobson: The protocol in this case su plies us with an abundance of information to substantiat the diagnosis of a large penetrating duodenal ulcer an

---

Presented at the Hennepin County Medical Society meeting, February 7, 1955.

Sponsored by the Minnesota Society of Clinical Pathologists.

Dr. Jackson is from the St. Louis Park Medical Center, and Dr. Smith is from the Veterans Administration Hospital.

leaves no doubt as to the wisdom of having advised surgical therapy for this patient's original disease. The preoperative information otherwise merely defines a relatively normal forty-one-year-old man. There was moderate hypochloremia and mild alkalosis probably related to the high degree of pyloric obstruction with vomiting. For reasons that are not well described he received blood preoperatively even though the hemoglobin is recorded as 13.5 grams per 100 cc. The ransfusion was complicated by what seems to have been an allergic transfusion reaction. There is nothing indicate that this was a hemolytic transfusion reaction.

The major problem began twenty-four hours postperatively and was manifested in the simplest analysis y the development of hypotensive shock and fever. The ifferential diagnosis must therefore include all postperative complications capable of producing rather severe shock and significant fever. The postoperative omplications must include diseases which might develop oincidental to the postoperative period and yet not be irectly related to the operation itself. In attempting o unravel this problem, I have elected to consider the arious causes of shock. The first obstacle to this aproach lies in the fact that there is no clear-cut classifiation of shock. From a purely physiological, pathological spect, all cases of shock are characterized by oligemia. y reduced peripheral resistance or by both. Therefore, is necessary to consider the causes of shock from a urely clinical standpoint. I have chosen five major nditions which could be the cause of shock. These re (1) hemorrhage, (2) administration of fluids or rugs, (3) operative complications, (4) overwhelming nfection, and (5) other medical diseases or complicaons. Although there might be disagreement and dispproval as to this classification there would certainly e complete unanimity of opinion relative to the imediate need for determining whether the shock was condary to hemorrhage. According to the work of merson and Ebert[1] during the second World War, is apparent that approximately 40 per cent of the ood volume must be lost in order to produce acute emorrhagic shock. It is obvious from this protocol, cluding the data relative to the patient's fluid reacement and the multiple recordings of hemoglobin er several days, that he did not lose any large amounts blood either at the operation on in the postoperative riod. Therefore, I believe that we can immediately smiss the factor of hemorrhage as producing the shock d complications noted in this patient.

I will turn next to the question of shock secondary the administration of drugs and fluids. Drugs are pable of producing shock as a result of one of three ctors, namely, (1) a primary hypotensive effect of e drugs, (2) the production of an acute anaphylactic action, and (3) the production of a delayed hypernsitivity reaction of the serum sickness type. Hexathonium and related drugs are common examples of bstances capable of producing marked hypotension and ock. This patient did not receive any drugs dinarily considered markedly hypotensive in their ect. The matter of acute anaphylaxis also seems extremely unlikely. The patient's reaction was delayed at least twenty-four hours, and also he maintained an adequate urine output during his entire postoperative course. Delayed hypersensitivity reactions of the serum sickness type, a common example of which is the penicillin reaction, is most frequently manifested by the delayed development of urticarial skin lesions, fever, arthritis and often gastrointestinal symptoms. Although shock is not a common manifestation of the delayed hypersensitivity reaction it may occur and I can recall one patient with profound collapse occurring during a severe penicillin reaction. There are, however, numerous reasons for excluding the hypersensitivity reaction of this type as the cause of this patient's postoperative manifestations.

The administration of fluids including blood may produce shock as a result of the infusion of potent pyrogens, as a result of bacterial contamination of the fluid or as a result of a hemolytic reaction. I will discuss the matter of bacterial contamination subsequently but at this time would believe that we could exclude either a severe pyrogenic reaction or a hemolytic transfusion reaction. The maintenance of an adequate urine output is the strongest single factor to consider in this regard. Of course, the lack of an elevated plasma hemoglobin further helps to exclude the possibility of a hemolytic transfusion reaction.

I probably would be prudent to omit entirely any discussion relative to postgastrectomy surgical complications capable of producing this picture. This requires a considerable knowledge of the technical aspects of the surgery which I am not at all prepared to discuss. However, I shall mention three things that come to mind, namely, (1) blowout of the duodenal stump, (2) ligation of a major artery at the time of surgery and (3) the development of a closed loop obstruction in the immediate postoperative period. I believe that the factor of time tends to exclude the possibility of a blowout of the duodenal stump. It is my understanding that this complication usually occurs about the fourth to the fifth postoperative day, and that it is relatively uncommon during the first twenty-four hours. The surgeons, I am sure, will object to the insinuation that they might during gastrectomy inadvertently ligate a major artery. However, I have considered three possibilities: (1) the middle colic artery, (2) the left hepatic artery, and (3) the celiac artery. I do not believe that ligation of any of these vessels would produce the picture noted in the postoperative period as recorded in this protocol. I have been told that one may ligate the middle colic artery without the development of arterial insufficiency and gangrene of the bowel. Ligation of the other two vessels might be expected to be more serious but not result in this clinical picture.

The possibility of a closed loop obstruction must however, be more seriously considered. In using the Billroth II operation, I believe it is common custom for the surgeon to place the tip of the gastric tube into the duodenal loop in order to maintain constant drainage and prevent the complication of a closed loop obstruction. It would be well to know at this time whether the gastric drainage in the postoperative period was bile stained.

Dr. Ralph Smith: The drainage was bile stained.

Dr. Jacobson: The presence of bile in the drainage fluid would appear to be the best proof that this was not a closed loop obstruction.

Severe overwhelming infections are not infrequently associated with the development of significant peripheral vascular collapse and shock. Actually the clinical manifestations of fever and shock presented by this patient strongly suggest the possibility of some severe complicating infectious process. A bacteremia usually complicates the infection in circumstances resulting in shock. Among the more common clinical infections capable of producing shock one must include pneumonia with bacteremia, meningococcemia, and urinary tract infections with associated bacteremia. Any of the coliform organisms capable of causing an acute pyelonephritis may result in bacteremia with fulminating shock and high fever. One must also consider the possibility of whether this patient received fluid or blood grossly contaminated with bacterial organisms. As you may already know, there have been reported by local authors at least two cases of acute fulminating shock and high fever associated with the transfusion of contaminated blood. In both of these cases the organism was a Gram-negative bacteria. The clinical picture has been well described by Borden and Hall.[2] The clinical state was one of immediate fever, shock and severe oliguria. This patient did not present this classical picture. I do not believe that there is evidence to suggest that he received contaminated blood; however, I cannot exclude the possibility of some other type of severe infection producing the picture of shock and high fever manifested by this patient.

In the final category I attempted to think of some other medical disease or medical complication capable of producing this syndrome. I considered two possibilities, (1) myocardial infarct and (2) acute pancreatitis. I think that it is wise whenever dealing with the problem of unknown shock to exclude the possibility of an acute silent myocardial infarct. I should like to ask, therefore, whether electrocardiograms were done on this patient during his postoperative period.

Dr. Ralph Smith: There were no electrocardiograms taken.

Dr. Jacobson: The absence of an electrocardiogram makes it more difficult to exclude the possibility of a myocardial infarct; however, I believe that we can rely on the clinical picture. It certainly would be unusual for an acute myocardial infarct to be manifested by fever of 103° to 105°, no pain and intermittent shock. For these reasons I shall eliminate this possibility for purposes of further discussion.

The development of an acute severe hemorrhagic pancreatitis during the postoperative period might adequately explain this patient's entire clinical course. It is known that this patient had a large duodenal ulcer and that preoperatively this had penetrated and probably to some degree had produced an associated pancreatitis. It is not unlikely, therefore, that this process could become acutely worse in the immediate postoperative period and result in a fulminating necrotic hemorrhagic pancreatitis.

The first question that comes to mind is, "How can one make a diagnosis of acute pancreatitis in view of the normal serum amylase?" In the usual case of acute pancreatitis the amylase will rise within the first twenty-four hours and will return to normal within three to ten days. The one exception to this rule is acute hemorrhagic pancreatitis in which there may be a transient rise during the first eight to twelve hours and then the serum amylase rapidly falls to normal and in some cases may fall to abnormally low values. It is not unusual in acute necrotic hemorrhagic pancreatitis to find values less than 50 units in the first twenty-four hours after the onset of the attack. It is well known that the elevation of the amylase is not correlated with either the severity nor the prognosis of acute pancreatitis. The elevation of the amylase in pancreatitis depends upon the release of pancreatic enzymes from the injured tissue into the circulation. If the gland is rapidly and completely destroyed and if there is associated thrombosis of the pancreatic and splenic vessels, it is readily apparent that there will be no release of pancreatic enzyme into the general circulation. On the other hand, cases of moderate necrosis may have high levels and the high levels may remain elevated for weeks after the acute symptoms subside.

The next question challenging this diagnosis is, "How can one make a diagnosis of acute pancreatitis in a man who has a soft abdomen with no unusual tenderness?" My only answer to this question is that this patient obviously has some fulminating intra-abdominal condition, and while it is unlikely in pancreatitis to have a non-tender soft abdomen, it would be equally unlikely in any other situation which I could consider. Furthermore, I have seen one previous patient who following a gastrectomy for carcinoma of the stomach developed a delayed renal shut-down which subsequently resulted in his death. During the entire postoperative period the patient had a soft, non-tender abdomen and yet at autopsy had a rather severe pancreatitis.

There are two studies which might have helped to shed further light on the possibility of this being acute hemorrhagic pancreatitis. First, we would expect in a patient with this complication some degree of peritoneal fluid, although not massive ascites. If some of this can be obtained by needle aspiration the determination of amylase value on the fluid may be extremely helpful in making the diagnosis of hemorrhagic pancreatitis. Even though the blood value may be low, the value in the secretion within the peritoneal cavity may exceed 500 to 1,000 units. Secondly, it is of extreme value to determine the serum calcium. This determination has its greatest value in the diagnosis and prognosis of pancreatitis in cases such as I would expect this to be, namely, acute hemorrhagic pancreatitis with the development of multiple fat necrotic areas throughout the peritoneal cavity. Under such circumstances, the serum calcium almost universally falls rapidly and falls to values of 7 mg. per cent or less. This determination, unlike the serum amylase, is directly related to the severity of the disease and is to some degree related to the prognosis. The lower the serum calcium value, the more likely the patient is to succumb to the acute pancreatitis. There is one other determination which might have been of some value, namely, the determination of the blood sugar level during the postoperative period. In patients with severe pancreatitis moderately severe hyperglycemia may develop.

In conclusion, I should like to state that I have reached this diagnosis probably more by intuition than by logic. The development of a severe pancreatitis might well constitute adequate grounds upon which the pathologists might justify their requesting an internist to discuss a "surgical case." I cannot exclude some overwhelming infection but am at a loss to more clearly define such a process and therefore will rest my differential discussion with the diagnosis of acute hemorrhagic pancreatitis.

Dr. Smith: Thank you, Dr. Jacobson. Are there any questions or discussion from the audience?

Member of Audience: I would like to suggest the possibility of infarction of the greater omentum which is usually left intact in the operation for benign ulcer.

Member of Audience: Another possibility in a case such as this, with a large penetrating ulcer, is erosion into the common bile duct, leading to an overwhelming ascending cholangitis.

Member of Audience: I find it difficult to believe that this is an acute pancreatitis in view of the leukopenia which is present.

Dr. Jacobson: As far as the leukopenia is concerned, all I can say is that whatever condition this patient has, the leukopenia will probably be difficult to explain. It is not uncommon, however, for many overwhelming inflammatory processes to result in a leukopenia.

Dr. Gleason: We had a lengthy discussion while we were preparing the protocol for this case, as to vhether to carry the history through to the death of he patient, or not. I suppose this may be criticized ut we finally decided to interrupt the history where we id to provoke more discussion.

The operation which was performed was an exploraory laparotomy, done to evaluate some of the possibiliies which Dr. Jacobson has discussed. There were about 00 cc. of blood-tinged fluid in the peritoneal cavity. The liver appeared somewhat darker and softer than sual but did not appear to be infarcted. All of the uture lines were intact and the anastomoses were atent. Exploration revealed only moderate distention f the small intestine, with no mechanical obstruction. There was no evidence of any localized nor generalized eritonitis. The pancreas appeared normal.

The patient remained in approximately the same eneral condition, with persistent vascular collapse, cyanosis, rapid pulse and rapid, shallow respirations. No other unusual signs or symptoms intervened, but the patient expired approximately twenty-four hours after the second operation.

Dr. Smith: Dr. Jacobson, would you care to make any further remarks, in the light of this additional history?

Dr. Jacobson: No thank you. I'll just sit back and listen.

Dr. M. Barron: Well, in order to defend Dr. Jacobson, I would like to ask why the surgeons thought it was necessary to operate. I didn't think it was pancreatitis but I didn't know what in the world it was. But what was the indication for operation?

Dr. E. Flink: I might add a word about that. Nothing that was being done seemed to be doing any good. The internists who were consulted on this case didn't have any good ideas, either. One thought that this was a Gram-negative bacteremia related to the indwelling catheter and one of the purposes of the operation was to do a cystostomy. The bladder was found to be quite normal. The hope was to find something that could be corrected.

Question from Audience: Were blood cultures taken?

Dr. Smith: Several blood cultures were taken and were negative.

Question from Audience: Were stool cultures taken?

Dr. Smith: They were taken but had not been reported on before death.

Autopsy Findings

Dr. Gleason: The heart and lungs were quite normal. The significant pathology was limited to the abdomen. There were 2,500 cc. of clear, straw-colored fluid in the peritoneal cavity. The peritoneal surfaces were smooth and glistening, with no evidence of peritonitis. The small intestine was of a peculiar rusty brown color, darker than normal. All of the operative sites were in good condition. There was only mild submucosal edema and hemorrhage in the inverted duodenal stump. The opened small intestine appeared normal to a point about two feet from the gastric anastomosis. Beyond this point the wall of the intestine was much thinner and softer than normal. The mucosa appeared to be absent and was represented by a practically complete, soft greyish white tubular cast lying free in the lumen of the intestine (Fig. 1). The entire small intestine was also moderately distended by a thin, cloudy, greenish gray liquid. No other abnormalities were found in the remainder of the examination.

Microscopic examination of the involved intestine revealed complete loss of the mucosal layer, leaving the muscularis mucosae practically intact, and there was only a mild subacute inflammatory reaction at the surface and extending a short distance into the submucosa, and a thin layer of inflammatory granulation tissue on the denuded surface.

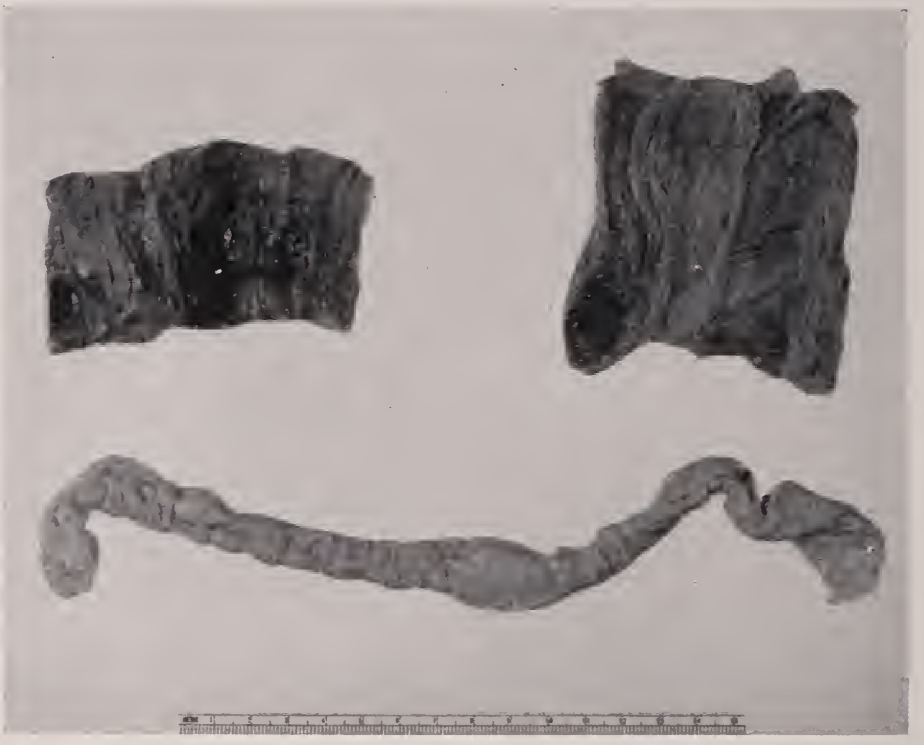

Fig. 1. Two segments of the small intestine, completely denuded of mucosa, and a portion of the soft cast found within the lumen of the small intestine.

Sections of the mucosal cast revealed that it consisted of an amorphous layer of fibrin and necrotic material in which there were embedded many mononuclear and polymorphonuclear leukocytes. During the last day of life rectal swab material had been cultured, at the instigation of Dr. Lyle Hay, who suggested the correct diagnosis. These were streaked on ordinary chocolate agar. As seen in Figure 2, there grew out an almost pure culture of an organism which was found to be a hemolytic staphylococcus aureus, coagulase negative. Only very few colonies of other bacteria were present on the slide. With this information, we went back to our microscopic material, and at only one point, on the inside of the tubular cast, could we find some of the luminal content adherent to the cast. In this there were numerous staphylococcal forms, sometimes in solid masses.

Our final diagnosis in this case is, of course, the syndrome of a staphylococcus enteritis causing a pseudomembranous ulcerative enteritis.

This is a condition which is not new. It was described in the American literature as long ago as 1893, as an occasional complication of gastroenterostomy for peptic ulcers. It is usually manifested clinically by what appears to be an acute peritonitis, with pain and swelling of the abdomen, nausea, vomiting, high fever and very severe shock. The usual case, of course, also presents a severe, watery diarrhea, which, however, may fail to manifest itself before death. It is this enormous loss of fluid and electrolytes into the lumen of the bowel in addition to the toxemia of the bacteria themselves, which causes the profound shock. Good analogies have been drawn between this syndrome and Asiatic cholera, and the same heroic water and electrolyte administration is required in the syndrome under discussion.

The pathogenesis of pseudomembranous ulcerative enteritis was unknown until recent years. Attempts to identify a causative organism were hampered by the use of selective media for the known pathogens, until it was finally appreciated that many of these patients had practically pure cultures of staphylococci in the intestinal content which were repressed by the selective media. The prevailing views now suggest that the staphylococcus comes to predominate in the intestinal flora when the normal conditions are disturbed by several factors, among which may be included intestinal obstruction, abdominal surgical procedures, many chronic disabling illnesses, and very probably the administration of various antibiotics which do not repress the staphylococci, or from the action of which the staphylococci may subsequently "escape."

It should be emphasized that this disease is not analogous to the bacillary dysenteries, in which much of the disability is due to tissue and blood stream invasion and liberation of endotoxins. It is more closely analogous to staphylococcal food poisoning in which preformed staphylococcal exotoxin is ingested in contaminated food and causes a violent gastroenteritis, while the staphylococci themselves do not invade the tissues, and in fact, do not even survive. In the present syndrome, however, the staphylococci are actually living within the lumen of the bowel and produce their potent exotoxins there. The pseudomembranous ulceration of the mucosa is probably produced by the direct action of these toxins and not by the organisms themselves.

I would like to say on behalf of the laboratory that you must be careful how you present this material to your bacteriologist if you suspect this staphylococcal enteritis. Do not ask him to culture for enteric pathogens. The highly selective media inhibit the growth of staphylococci. Do not ask him to "culture for staphylococci." He may use a selective medium for staphylococci. Almost all fecal material contains appreciable numbers of staphylococci. It is essential to establish that the staphylococci are the *predominant* organism. Examination of a direct smear may give strong confirmation of your suspicion if the smear is loaded with staphylococci. The material should be streaked on ordinary blood or chocolate blood agar and examined for the predominant organism.

Sensitivity studies should be carried out promptly. Treatment of the water and electrolyte problem should be instituted immediately, but an antibiotic must be found which will control the staphylococci. In our case, the organism was resistant to all the antibiotics which were being used, but it was sensitive to erythromycin, which incidentally is probably the antibiotic of choice in this community in which staphylococci resistant to other antibiotics are rapidly increasing in numbers.

Finally, it should be noted that some apparently identical cases of this syndrome have failed to yield staphylococci, and other organisms may apparently cause a similar enteritis.

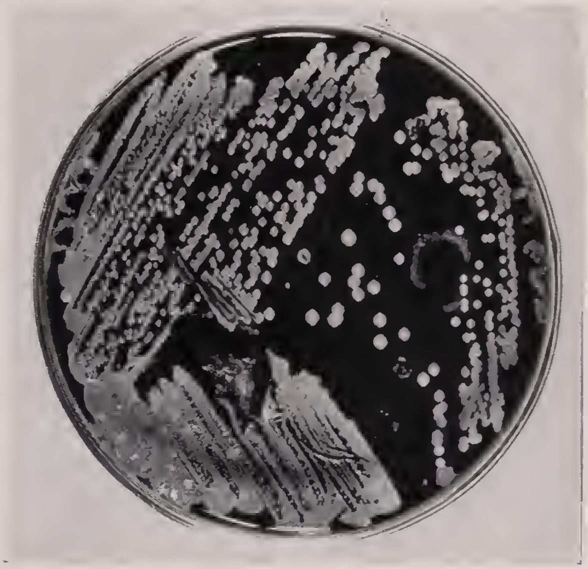

Fig. 2. Photograph of the chocolate agar culture of the rectal swab. Practically pure culture of staphylococci.

THREE PER CENT OF AIRLINE PASSENGERS ARE AMBULATORY PATIENTS

An estimated 3 per cent of all passengers flown by regularly scheduled U. S. airlines pose a unique problem for transportation officials and physicians—unique because they are ambulatory patients who must travel as ordinary passengers.

Maj. Gen. Harry G. Armstrong, U. S. Air Force surgeon in Wiesbaden, Germany, discusses "Air Travel and the Ambulatory Patient" in the current *International Forum,* a supplement to *Therapeutic Notes* published for physicians by Parke, Davis & Company.

"During 1954, it is estimated that approximately 1,000,000 of the 34,500,000 passengers flown by the regularly scheduled airlines of the United States were suffering from some disease or disability," he says.

Gen. Armstrong writes that the figure shows physicians are constantly being asked to advise their patients on the effects of air travel. He adds that "all clinicians should be fully qualified to deal with this subject."

Health laws and transport regulations, flight safety, and the possible effects of aerial environment on the patient, he explains, all are factors which must be considered by both the physician and the airlines.

Because of strict Civil Air Regulations, Gen. Armstrong says, "We can predict fairly accurately the type and degree of deviation from normal to which a patient traveling by air may be subjected."

However, he points out that there are several "deviations" which must be considered in each case.

"The first is air sickness, which is clinically identical with carsickness, trainsickness, and seasickness, and thus, is not peculiar to flying."

Gen. Armstrong says oxygen deficiencies and expansion of body gases also are factors for the patient and his physician to consider. He emphasizes the advising physician must determine whether any of these factors would have a detrimental effect on the primary disease.

However, Gen. Armstrong points out that many physicians have been "unnecessarily restrictive in permitting cardiac and respiratory patients to travel by air."

"Identification of those who should fly is relatively simple, if airline flight procedures are understood. In questionable cases, the medical director of the airline concerned is qualified to provide expert opinion and guidance," he says.

LISTENING ABILITY AND SUCCESS

There is a belated but very real awakening in American education today to the fact that effective listening means learning economy, increased industrial efficiency, and better professional relationships. *Belated,* because many years have passed since Dr. Paul Rankin's research in which he reported that about 70 per cent of our waking day is devoted to verbal communication, and that 45 per cent of that verbal communication is devoted to listening. *Very real,* because more and more we are recognizing that reading and listening are our two great and basic media of learning, and that the latter as well as the former must be given direct attention in school.

One evidence of current interest is found in higher education. Seven years ago but one college was teaching listening; today, at least twenty-two of our leading colleges and universities provide this type of instruction. Furthermore, they are conducting, in all, about twice that number of related, graduate-level research projects in an attempt to discover how listening ability can be improved. Such studies should soon decrease the disparity between past research in reading and listening comprehension. Seven years ago more than 3000 studies related to the former had been published; only fourteen related to the latter had appeared.

Two volumes just published by the Curriculum Commission of the National Council of Teachers of English reveal the present concern of persons in elementary and secondary education. Considerable space is devoted to basic listening skills. Dr. Dora V. Smith, chairman, seems to point the direction our schools are most likely to travel when she declares: "It (the Commission) believes that mastery of the skills of reading, writing, speaking and listening is basic to the American way of life and cannot be subordinated to any other aspect of the school program."

Perhaps the most dramatic recognition of the importance of ability to listen has been by management personnel in American industry. A somewhat sudden realization a few years ago that there are clear-cut dollar values in having employes who listen well has resulted in the institution of a number of training programs designed to achieve that end. Among the first firms to take such action have been American Telephone and Telegraph, The Methods Engineering Council, General Motors, The Dow Chemical Company, The Wood Conversion Company, Minnesota Mining and Manufacturing, and many others. The number is steadily increasing. As Frank E. Fischer, Director of the Communications Course of the American Management Association, has put it: "Efficient listening is of such critical importance to industry, that as research and methodology improve I feel that training departments will have to offer courses in this field."

Within a few years, one of the first steps an employer will take when considering a new employe will be that of verifying the latter's listening index. This index will be derived from standard tests of listening comprehension already available and on the market. The next move—an entirely reasonable and desirable one—may well prove to be the use of the listening index as an additional criterion for the screening of candidates for medicine, law, or other types of professional training.

Professor of Rhetoric
University of Minnesota

STEROIDS AND ARTHRITIS

Hench, Kendall, Slocumb and Polley announced in 1949 the potent effects of ACTH and cortisone on rheumatoid arthritis and related conditions. The vast experience of the past six years with these preparations and subsequently developed derivatives has substantiated and extended the early reports. The steroids are of proved value for systemic use in the treatment of rheumatoid arthritis and arthritis associated with other systemic diseases, such as rheumatic fever, in the treatment of lupus erythematosus and drug sensitivity and occasionally in the symptomatic management of the acute painful shoulder. The steroids are less satisfactory for systemic use in the long-term control of the episodic type of rheumatoid arthritis and palindromic rheumatism because of difficulties in adjusting dosage. These hormones are not of value for systemic use in osteoarthritis and should not be used in specific infectious arthritis.

Much has been published concerning the metabolic changes seen in short-term therapy with the steroid hormones. These metabolic effects develop more quickly with excessive dosages and occur nore readily in women than in men. Postmenopausal women and preadolescent children require a smaller dose than men for therapeutic effect and are especially susceptible to the effects of overdosage. Reversal of these changes is much slower in patients who have taken steroids for more than two months than in those who have taken them for ess time.

A systemic reaction occurs in many patients given these steroids in excessive doses for prolonged periods for control of rheumatoid arthritis. This eaction is characterized by emotional instability, atigability and generalized aching, in addition to one or more of the clinical changes typical of Cushing's syndrome. If such a reaction is not recognized and managed by gradual reduction of dosage in addition to conservative management of he systemic illness, a mesenchymal reaction simulating lupus erythematosus or periarteritis nodosa may develop. Such mesenchymal changes may be mistaken for a flare of the arthritis.

The steroids should be used as an adjunct to he accepted conservative methods of treatment of heumatoid arthritis, namely, rest, physical ther-py and salicylates. Systemic steroid therapy for heumatoid arthritis is usually most effective when he smallest possible daily dose needed to suppress he systemic disease is administered in divided oses of relatively equal portions every 6 to 8 ours. Caution is necessary to insure that the eroids are not used primarily as analgesics to low excessive use of damaged joints. Intra-rticular injections of steroids may be of benefit in dividual selected instances.

The development of analogues of cortisone pro-ucing anti-inflammatory effects with somewhat ss alteration of electrolytes encourages hope for mproved steroid therapy with even more selective fectiveness for certain types of arthritis in the ture.

JOHN G. MAYNE, M.D.

SALESMANSHIP

How many new and valuable ideas, inventions, developments and theories have been lost to the world because of lack of skill in properly presenting their merits, thus defeating their acceptance by others and the world at large?

Whether the nature of our work be an avocation or along professional lines, would it be too broad a statement to say that if our efforts are to be successful resulting in accomplishment, there is a requirement on our part of salesmanship in its true sense?

Should we agree—then "What is salesmanship?" Is it the blatant haranguing of the "barker?" Is it the horse-trading instincts of the "Yankee peddler" — the fast-talking, boisterous-living, flashily dressed "drummer," all of whose characteristics in the minds of many frequently continue to be associated with the term salesman?

It is none of these. Under present-day circumstances, their methods would fail to succeed. Because of modern newspaper circulation, circulation of magazines, trade journals, scientific journals, expansion of education, radio, television and increasing ease of travel, communication has expanded far beyond that of the past. Thus, distribution of ideas, services and goods has developed into a higher science in meeting the requirements of our changing world.

Perhaps it is too general in comprehensive definition to say that salesmanship is the skill by which ideas, services and goods are properly presented to others and the world at large. Perhaps it would be better to say it is the measure of "wit" by which we present our offerings to the world.

Wit is one of the most important tools of selling. It would be worthwhile for everyone to review carefully the definition of "wit" in Webster's Unabridged International Dictionary which employs a full column of fine print for the purpose. It will be noted that "wit" should not be confused with its synonym "humor." Humor commonly implies broader human sympathy but does not imply all of the meaning of "wit," since "wit" is more purely intellectual, embodying humor only when required.

In the objective of gaining the acceptance for our ideas, services or goods offered, we must first have a thorough knowledge and background of our subject. It is then that our skill or wit comes to play so that logically and intelligently we portray and properly present what we desire to offer. Our aim is to influence people to think as we think, to desire as we wish them to desire.

The style of presentation must be altered and suited according to our estimation of the personality or personalities whose attention we wish to obtain. This is necessary, if we are to gain acceptance for our proposal. Thus we must maintain a flexibility in our approach since individual personalities are as different as human nature provides.

For example, a technical man may freely discuss his subject with another technical man in the understandable terms of his profession. Should he similarly discuss the same subject with one who has no technical training, he may sound impressive but would not be understood. To the latter, we must translate our presentation into simple layman language if our point is to be made.

In any walks of life, an expert thoroughly skilled in his subject but who shows intolerance toward any except those whose knowledge is equal to his own will seldom develop many friends. The expert who listens with patient interest to the views of all others before expressing his own ideas makes closer friends, develops their confidence and will have more of his views accepted. It is he to whom most people will wend their way for advice.

Where our objective is to gain an acceptance for what we have to offer, be it ideas, services or goods, we must develop in the mind of the listener the value it has for him and his desire to have it. In so doing, we must with friendly attitude develop a confidence in what we are offering and in ourselves. Thus we must show an honest and sincere interest in our product and an enthusiastic belief in the value we are attempting to share or have accepted by others.

We must show an unselfish and willing interest by backing our offering with our personal service, thus bringing to attention our personal interest to extend the best benefits of our offering. We must honestly give, in order to get.

For centuries the Chinese have gained a reputation for showing great aversion toward change. Is this a characteristic limited alone to the Chinese?

There is evidence of considerable reluctance on the part of all of us to exchange established habits and ideas for new habits and new ideas. Th applies equally to services and developments well as to brands and types of goods.

Whether we are offering ideas or services or hav the avocation of distributing goods, there is requirement for a high type of salesmanship in a of its ramifications. By our skill or wit, we ma properly present the better values, the new cor cepts of that which we offer if their acceptanc is to be obtained.

Regardless of the path of our work or effor our success and accomplishments depend on thi

Joseph C. Duk

ACTIVITIES OF THE MEDICAL TESTIMONY COMMITTEE

The Medical Testimony Committee of th Minnesota State Medical Association, appointed i 1940 by the President and Council of the Association, has a history of marked accomplishment t its credit.

During the fifteen years of its existence, th committee has investigated the expert medica testimony of thirty-three physicians, about whor a complaint *in writing* was submitted to the committee. At each investigation, the committee ha the assistance and opinion of three specialists i the particular field of medicine involved. In si cases, the testimony was found satisfactory, an the physician was not informed about the investigation. In seventeen cases, the testimony wa found somewhat questionable or over-enthusiastic and the physician under investigation was interviewed by a member of the committee. Th committee's decision and the opinion of th specialists were discussed with each physician, an the results in sixteen cases were very satisfactory In the seventeenth case, however, there was n improvement in the physician's expert testimony and with the next complaint his case was referre to the Minnesota State Board of Medical Examiners for disciplinary action, as were nin others, in which the testimony was of a very seriou nature. In one case, the report was sent direc to the Judge of the Supreme Court who ha requested the examination. This testimony wa very questionable.

During the early years, several requests for investigation were received from physicians. Durin the past five years, only one request has bee submitted by a physician. All others have com from members of the Bar Association. In order to avoid any embarrassment, *no one except the chairman* of the committee has any knowledge of the source of a request for an investigation. Assuredly, the committee does not have a pleasant job, but a serious and uncomfortable duty. In order that the committee may function properly, it is of the utmost importance that the members be kept informed about any questionable expert medical testimony. Only by that means can the committee keep expert medical testimony on a high level in the courts of the state.

The work of this committee has received recognition throughout the United States from other State Medical Societies, as well as from legal societies, law schools, and other organizations. In a recent book on "Legal Medicine," an entire chapter is devoted to the activities of our Minnesota Medical Testimony Committee.

E. M. Hammes, M.D.
Chairman, Medical Testimony Committee

BLUE CROSS AND "TAKE-HOME DRUGS"

Under the Blue Cross contract, the patient pays or "take home drugs."

In the Schedule of Benefits in the Blue Cross contract, Benefit 11 specifies:

> "Drugs, biologicals and solutions used in the hospital and listed in the latest edition of the United States Pharmacopoeia, The National Formulary or New and Non-Official Remedies, except blood and blood plasma."

The phrase "used in the hospital" contained in his benefit means just what it says. To be overed by Blue Cross, drugs must be used in the ospital; drugs taken home or used outside the ospital are also outside the scope of Blue Cross overage.

However, recent audits of hospital records have nown some misunderstanding as to who is respon-ble for payment for "take home drugs." In ertain instances, "take home drugs" had been ncluded in the Blue Cross billing, and Blue Cross ad covered allowances on these cases. To rectify me such situations, it has been necessary for lue Cross to recover substantial sums from the ospitals involved as reimbursement for these ake home drugs" that had been included on the lue Cross bill and that were not covered by the lue Cross contract.

To prevent hardship on the hospital, it is most important that great care be exercised in designating and segregating "take home drugs" from drugs used by the patient in the hospital. If a misunderstanding occurs and Blue Cross is charged for "take home drugs," the hospital is placed in an embarrassing and in a costly position at some future date when such a misunderstanding is discovered, and it is necessary for the hospital to reimburse Blue Cross for the "take home drugs" for which Blue Cross has been billed and has paid. In this situation, the hospital is faced either with the alternative of going back to the patient to collect for these "take home drugs," thus running the risk of poor public relations, or of bearing the expense of such "take home drugs" itself.

Blue Cross is co-operating with the Minnesota Blue Cross hospitals in providing the hospitals with stamps indicating "take home drugs" that the hospitals can use on their records. If care is used is designating and segregating "take home drugs," no "take home drug" problem will arise for either the hospitals or Blue Cross.

Director of Hospital Relations,
Minnesota Blue Cross

WHO WILL BECOME AN ALCOHOLIC?

There are warning signs for the potential alcoholic person which appear during and after drinking. A person disposed to alcoholism drinks consciously and purposely for the effects of alcohol on his feelings and attitudes. These feelings may be vague and hard to define, such as a dim awareness of being ill at ease.

On the surface he appears to be well adjusted, but it is a borderline adjustment. He may eventually lose complete control over the time and amount he drinks. He is filled with remorse about what he did yesterday, and he is worried sick about what tomorrow will bring.

Sometimes a person may drink to escape worries or troubles. At a party, he may sneak a a few "quick ones" to steady his nerves. He may have a fixed time for drinking and feel uncomfortable if he misses it. He may find himself thinking more of the drinking than the sociability which goes with it. He may start to lie about his drinking. He may have long periods of sleepless-

This is the second in a series of four editorials on the subject of alcoholism.

ness. He may become unjustifiably suspicious or jealous. He may slip himself a drink in the morning. He may start to "get tight" oftener. Then, eventually, he may go on a spree after which, ashamed, he resolves not to drink again. Sooner or later, though, his "nerves" get the better of him, and he takes another drink. This starts another spree. *He may "pull a blank" or "black out."* He may have vague, nameless, constant fears. *These are the storm warnings.*

DOCTORS—NOT TIME—SHOULD MAKE THE DIAGNOSIS OF CANCER

We have an instinctive belief that many physicians will not receive with enthusiasm the 1956 campaign slogan of the American Cancer Society which emphasizes periodic medical checkups and is designed to increase the number of examinations of presumably "well" people.

There can be no direct criticism of the American Cancer Society for favoring periodic examinations of apparently well people. Its position is strongly arched and buttressed by the overwhelming support of the clear-thinking leaders of the medical profession, the force of public opinion, and sound statistical arguments.

Medical objections to the program will be expressed by negativism and arguments which circumvent the facts, and will come from physicians who have not adjusted their practices to include a place for the patient who wants a periodic checkup.

It is understandable that physicians are not generally enthusiastic about periodic examinations of apparently well people. Frankly, we have been thoroughly bored by a deluge of routine examinations: army, insurance, industrial and "what-have-you." We accept, in principle, the value of such examinations but we tend to consider them as necessary evils which mar the pleasures to be derived from practicing a profession. Our enthusiasm is kindled chiefly by the challenge of such matters as a difficult diagnostic problem, or the cure of a seriously ill patient by the skillful use of our knowledge and skills.

While meeting the challenge of skillful diagnosis and therapy, perhaps too many of us are overlooking an equally challenging field of medicine. Up until now, we have been content to settle for a diagnosis of symptomatic cancer, after the differential exclusion of other diseases which cancer so slyly mimics. Actually, though, *time* has made the diagnosis for us: the patient with a symptomatic cancer has had the disease for as long as several months to several years before we see the obvious! The real challenge of the future is the skillful diagnosis of the asymptomatic cancer in the "well" person.

We suggest that a thing seriously pursued affords true enjoyment. That portion of a busy medical practice which is devoted to the searching examination of an apparently well patient who wants to know "Do I have cancer?" is truly enjoyable if seriously pursued.

The dividends are many and rewarding: the gratitude of a patient who can get a satisfactory answer to a vexing question from his personal physician—a patient who will come back again; the frequent detection of latent disease unrelated to cancer, and, though the yield is small, an occasional diagnosis of curable cancer before *time* has made it obvious. Doctors—not *time*—should diagnose cancer.

Chairman, Cancer Committee, MSMA

RADIATION PROTECTION FOR THE TECHNICIAN IN TRAINING

Emphasis, at the present time, on radiation protection of the entire population seems to make necessary re-evaluation of procedures which in the past were considered acceptable. The concept of tolerance dose of radiation is now redefined (National Bureau of Standards Handbook 59) as a "tolerable" dose. This is intended to convey the concept that all radiation is damaging and that there is no such thing as a dose which will produce no damage. The "tolerable" dose is that which can be accepted without any *detectable* damage within the life span of the individual.

On the basis of this concept, it is the responsibility of all individuals, schools, and hospitals who utilize and teach x-ray procedures to eliminate, wherever possible, unnecessary exposure to x-radiation. No longer can one justify utilizing students as "patients" in teaching x-ray technique. No radiographic procedure using a student as patient can be considered acceptable unless the end results of the procedure are medically useful for the individual patient (as, for example, the routine chest film required on admission to the school).

On the basis that the school can no longer justify what might rightly be termed "spending part of the tolerable lifetime radiation dose" for the student, how can a school not connected directly with a hospital or supply of patients teach x-ray technique properly without using students as patients?

There are readily available substitute materials which can be used to teach x-ray physics, radiographic exposure techniques, etc. Untempered masonite suitably replaces water equivalent tissue (as the abdomen). Plywood has a density equivalent to the thorax. Use of these materials will reduce considerably the necessity for using patients during the early part of the technician's training. Anatomy, radiographic anatomy and positioning for radiography can be taught without energizing the x-ray machine. The final stage of training, in which the procedure on the patient is necessary, will then not be possible in the school, unless arrangements can be made with a clinic or a hospital.

On the basis of recent interpretations of tolerance dose of radiation, it is the opinion of he writer that the time has come to consider nnecessary exposure to the technician in training s a removable hazard and to move to condemn uch practices *in toto*.

James F. Marvin, Ph.D.
Radiological Physicist

VHAT CONSTITUTES THE PRACTICE)F MEDICINE?

An official answer to a problem harassing both hysicians and hospital Boards of Directors over he country was sounded for the third time in nore than a decade before the House of Deleates of the American Medical Association at the oston Clinical meeting last November. The eport of the committee on Medical Education and Hospitals which was approved by the delegates follows:

> Whereas, The American system of private practice of medicine has given us the highest health and medical standards in the world; and
>
> Whereas, The American Medical Association has publicly declared its stand in favor of this system of private practice; and
>
> Whereas, The practice of pathology, including both clinical and anatomic pathology, is the practice of medicine; and
>
> Whereas, In many states the attorneys general have written opinions stating that the operation of laboratories and departments of radiology and anesthesia by corporations, including hospitals, is illegal, and that the acceptance of employment from such corporations by a licensed practitioner of medicine under terms permitting the corporation to charge a fee for his services is unethical fee splitting and illegal; and
>
> Whereas, As a result of such interpretations attempts are being made by certain lay groups to amend the laws, or their interpretations, to permit the division of pathology into professional and technical services, the latter to be the work of the pathologist's technical assistants who perform under his direction and supervision and not to be considered the practice of medicine and, therefore, services which may be legally performed by a hospital; and,
>
> Whereas, If this position should be sustained, fragmentation of the practice of pathology would be accomplished and thus all medicine would be in danger of being so divided to the detriment of the patient; and
>
> Whereas, As early as 1943 the American Medical Association studied this problem and stated that the "House of Delegates of the American Medical Association is opposed to the division of any branch of medical practice into so-called technical and professional factions," and later, in 1951, that "the practice of anesthesiology, pathology, physical medicine, and radiology are an integral part of the practice of medicine in the same category as the practice of surgery, internal medicine, or any other designated field of medicine"; therefore be it
>
> Resolved, That the House of Delegates of the American Medical Association is opposed to the division of any branch of medical practice into so-called technical and professional services; and be it further
>
> Resolved, That because of the confusion existing in some states in regard to this question this House of Delegates reaffirm the position taken in 1943 and 1951.

President's Letter

MINNESOTA AND THE AMERICAN MEDICAL EDUCATION FOUNDATION

The National Fund for Medical Education was founded in 1951 for the purpose of securing voluntary contributions from industry, medical associations and individual physicians to help meet the rising cost of medical education. It was estimated that $10.000,000 annually in additional funds were needed by our eighty-one medical schools, if they were to maintain their high standards of teaching and research. The American Medical Association undertook to raise $2,000,000 of this amount annually from the physicians of the nation, on a voluntary contribution basis. The AMA generously contributed $500,000 annually for the years 1951-54, inclusive, then in 1955, reduced their contribution to $100,000, believing, that as the individual physicians became aware of the need, they would make up the difference. The AMA, in 1951, set up the American Medical Education Foundation as an agency to solicit and collect the physician's share of the voluntary contributions, and agreed to pay all operational costs of the agency so that every dollar contributed would be turned over to the National Education Fund to be distributed to the Medical Schools.

Minnesota, as did most of the other states, got off to a slow start. From 1952 to May, 1955, Minnesota doctors had contributed only $27,000. Minnesota's share of the needed $2,000,000 would be about $40,000 annually.

In 1954, 138 Minnesota doctors contributed $5,890.38. In 1955, 588 doctors contributed $17,147. In May, 1955, our House of Delegates voted to support the plan of Dr. H. E. Drill, State Chairman, to solicit on the County Society level with a chairman in each county society and a councilor district chairman to co-ordinate their activities. In September, 1955, Dr. Drill called a meeting of all the county chairmen and councilor chairmen at St. Paul for purposes of information and organization of a definite campaign period.

I am glad to report to you that as a result of this effort, Minnesota doctors are doing much better. In January, 1956, 248 contributors gave $7,590 and 142 contributors gave $2,996.75 in February, 1956, or a total of $10,733.75 in two months. But that accounts for only 390 contributors out of our membership of approximately 3,000, roughly 12 per cent. What has our Medical School received in return from the National Fund? In 1954, the University of Minnesota Medical School received $35,762.75, and total grants to January 1, 1955, have been $102,718.75. The 1955 figures are not yet available.

The week of April 23-29, 1956, has been designated as National Medical Education week, of which you will hear much more in the immediate future. I trust you will all participate in the week's activities in your respective communities and will become inspired to join the increasing numbers contributing to the American Medical Education Foundation in our state.

R. H. Wilson

President, Minnesota State Medical Association

Medical Economics

Edited by the
Committee on Medical Economics,
Minnesota State Medical Association
George Earl, M.D., Chairman

COUNTY SOCIETY OFFICERS MEETING

The County Society Officers meeting in Saint Paul on February 25 dealt with three aspects of the current medical scene of interest to Minnesota doctors. They were "Medical Care for the Indigent," "Insurance Plans for Members" and "National Legislation and the Medical Viewpoint."

Medical Care for the Indigent

Dr. C. L. Oppegaard, chairman of the Council, described the history and development of medical care for welfare patients in this state. He spoke of the improvement of medical care from the old county physician days to the present day program where all relief clients have the free choice of doctor; it is this approach for which the state association has fought, though it was not adopted until the special session of 1937.

Those people who are receiving aid today are getting excellent care and all concerned can take justifiable pride in solid progress. However, it is difficult to keep rising costs under control while carrying on a program of good medical service. Dr. Oppegaard said:

> "Remember, the alternative to willing and zealous co-operation on the part of the doctors of the state may well be new bills to cut costs; bills that will not only cut costs, but cut medical service to the point where the good work of years will be undone. So costs *must* be cut. At the same time standards of service *must* be maintained. Those are the two horns of our dilemma. We must ride them both, if we are not to sacrifice the progress achieved over many years in our system of medical care for the needy sick."

Mr. Morris Hursh, Director, Department of Public Welfare, praised the close and pleasant contact his office has had with medical groups in Minnesota: the Council and members of the Minnesota State Medical Association; Dr. R. H. Wilson and the members of the State-Wide Medical Advisory Committee.

The rising cost of medical care to welfare patients has been of great concern to the Department of Public Welfare and the Legislature. In 1955 the Legislature decided that (1) no type of medical care should be paid for by the county unless it had been authorized by the County Welfare Board and (2) maximum fees should be established for every kind of care, including drugs as well as medical procedures.

Mr. Hursh felt that prior authorization was sound business practice, but that the setting of fees was already being done by the State-Wide Advisory Board. However, on April 1 the new maximum fee schedule, the same schedule used by Blue Shield Plan A for medical and surgical care, and by Blue Cross for hospital charges, will go into effect.

Though doctors' fees account for only 12 per cent of the total welfare bill, doctors hold the key to the success of the program, because it is their responsibility to authorize hospital and nursing home care. Fee schedules for individual counties will be worked out separately and it is important to remember that the schedule is a maximum.

Prior authorization is sometimes difficult to handle, especially when it is necessary for a patient to remain in the hospital for thirty days or longer. One benefit that results from this requirement, however, is that hospital stays are being shortened, which might be a big factor in bringing down welfare costs.

Regarding the general principle of welfare care, Mr. Hursh emphasized that no one wants to give less adequate care to welfare patients. Also, that rising costs should not be a surprise: as the lengthened life span increases the proportion and numbers of elderly persons, the situation will get worse, and cutting welfare services is not realistic.

President R. H. Wilson, until recently chairman of the State-Wide Advisory Committee of the Division of Public Welfare, said that inflation and the growing geriatric problem accounted largely for the rising costs of medical care to the state. The mean age of recipients is seventy-seven years in Minnesota.

According to Dr. Wilson, prior authorization for medical care creates a problem of much additional time and labor on paper work. And, not being doctors, county boards cannot conscientiously refuse medical care that a physician has requested.

The decision reverts to the medical advisory committee, whose members judge the necessity for the care and eliminate unnecessary care.

Prior authorization for hospitalization is a different matter. It works well in limiting the length of time patients stay in the hospital and reduces hospitalization costs. A further reduction will show up when nursing home care has been limited.

Dr. Wilson commended the co-operation of the Department of Public Welfare and said that though a state-wide uniform fee schedule was considered more desirable, most doctors are not dissatisfied with the new maximum schedules where each county welfare board and county medical advisory committee negotiates individual county rates. The State-Wide Medical Advisory Committee approves county schedules, but does not enter into the negotiations, he emphasized.

GROUP LIFE INSURANCE

Mr. A. R. Hustad, Northwestern National Life Insurance Company, explained the program available to Active and Resident members. Members who are sixty-five or younger are eligible for $5,000 insurance and members who are sixty-six to seventy-five are eligible for $2,500 insurance under certain conditions. Premium rates are very low; for example, the annual premium for $5,000 insurance for a man of thirty-five is $34.50.

Members of component societies where the plan has been accepted can take out the insurance at any time, if they are insurable. Also, any member of one of these societies can take out insurance until May 1 without a physical examination, provided a total of 100 members from qualified societies enroll.

New societies can participate in the plan this year without a physical examination being required of applicants, provided seventy-five per cent of the active members enroll.

A complete discussion of malpractice insurance will appear soon in Minnesota Medicine.

NATIONAL LEGISLATION

Mr. C. Joseph Stetler, Director, Law Department, AMA, described AMA activities with regard to national legislation. Of the 12,000 bills introduced at the first session of the 84th Congress, 400 of them had some connection with medicine.

Seventeen people employed in the Washington office of the AMA spend most of their time answering inquiries from Senators and Representatives. Other duties include arranging for medical witnesses on proposed legislation, preparing testimony, and studying bills.

The cornerstone of the health proposals of the Administration is a program for medical research and one-time grants to medical institutions. Since opposition had been to maintenance support that would eventually give the government a voice in management and policies, this program is not considered objectionable.

Discussion of shortages in the medical field is no longer concentrated on doctors: nurses and certain specialties are listed as being short of qualified personnel.

Greater emphasis has been placed on removing the obstacles in the way of private companies handling poor health insurance risks. Reinsurance as a government issue seems to be dead.

It has been proposed that the Hill-Burton Act be extended for two years after 1957 when it was to expire. The AMA feels that the time has come for an appraisal of what has been accomplished with this act; to see if it has fulfilled its purpose and to judge whether it is the best answer to the problems in the field of hospital construction aid.

The Defense Department has a bill that would offer greater incentives to induce more doctors to make a career of the service. This is being supported, though it does not go far enough to be fully effective. Some bill dealing with doctors in service will be passed and it is to be hoped that it will be more effective than the present one.

Congress is now considering a bill that would authorize commissions for osteopaths in the armed forces. If this bill should become law, it would mean that osteopaths would share the same responsibilities that M.D.'s have as medical officers; servicemen would not know what training the doctor treating him had received. This, of course, would wreck any plan for an incentive program for M.D.'s.

Several approaches to the question of medical care for military dependents have been suggested. The AMA takes the position that care for military dependents at military facilities and by military personnel should be restricted to overseas establishments.

Mr. Stetler underlined the fact that though the AMA can evaluate legislation and alert the profession to bills inimical to the welfare of medicine and the country as a whole, their main function is to provide information for Congress and other departments of the government.

SEARS FOUNDATION CONTINUES PRACTICE GRANTS

The Sears-Roebuck Foundation has announced that it has allotted $125,000 to continue its program of long-term, unsecured loans to physicians to help them set up practice units. Greater emphasis will be placed on locating doctors in communities without medical care.

Last year the Foundation assisted in establishing ten units, some to retain existing facilities in areas about to lose them. Loans range from $3,000 to $25,000 to applicants screened and selected by a seventeen-man advisory board of physicians named by the trustees of the AMA. Dr. J. A. Bargen, Mayo Clinic, is the member from this region. This year a minimum of $149,000 will be available for the program.

Mr. Theodore V. Houser, president of the Foundation, has said:

> "Some of the criteria for evaluating requests for assistance will be the professional qualifications of the applicant, the availability of medical service in the community, the extent of community participation in establishing the proposed unit, and the soundness of the plans proposed for providing medical care."

He emphasized that loans will not be made for the purpose of refinancing current obligations.

Grants are repayable any time within ten years, with payments being made in equal monthly installments starting not later than the beginning of the fourth year. Until repayment is begun, interest is charged at the rate of 6 per cent per year, payable monthly. No interest is charged after repayment begins. After the fifth year when interest payments have ceased, recipients make monthly contributions to a revolving fund. This is in recognition of the aid they have received and to assist other physicians.

All interest money and pledge money, along with all repaid loans, is used for the purpose of establishing additional medical practice units. The addition of these funds to the basic amounts provided by the Foundation will enable the plan to grow, Mr. Houser said.

MINNEAPOLIS MAN SENTENCED FOR VIOLATION OF BASIC SCIENCE LAW

Re: State of Minnesota vs. Lafayette M. Gray

On February 18, 1956, Lafayette M. Gray, eighty-one, 5025 Queen Avenue South, Minneapolis, was sentenced by the Hon. John A. Weeks, Judge of District Court of Hennepin County, to a term of 30 days in the Minneapolis Workhouse following Gray's plea of guilty to practicing healing without having a basic science certificate. However, Judge Weeks suspended the sentence on condition that the defendant refrains in the future from selling Powdr-X and that he surrenders his supply of Powdr-X to the authorities.

A complaint had been issued on February 9, 1956, charging Gray with the above offense after he had examined a Minneapolis woman and recommended his product Powdr-X for her condition, making a charge of $3.00 for a can of the powder. Gray told the woman that Powdr-X would "pep up her appetite" if taken internally, and for her eye condition he recommended that she put a teaspoonful of it into a glass of warm water and after letting it settle, use the liquid in an eyecup three or four times per day.

The defendant has a previous conviction in United States District Court in Minneapolis on March 22, 1950, when he was sentenced by Judge Gunnar H. Nordbye to pay a fine of $1,000.00 following Gray's entering a plea of "nolo contendere" to two counts in an information charging him with violating the Federal Food, Drug and Cosmetic Act. Gray had been convicted by a jury in the same Court on March 27, 1948, of introducing in interstate commerce at Minneapolis, a number of packages containing a drug called Powdr-X, and it was charged that a letter accompanying the shipment contained the following statement: "In fact it is an ointment that is splendid for almost any infection, abrasions, or ulcers." It was further alleged that the drug was misbranded in that the above statement was false and misleading because the drug is not efficacious in the cure, mitigation and treatment of infections, abrasions or ulcers. Following his conviction by the jury, Gray appealed to the United States Circuit Court of Appeals, which Court reversed the conviction because of errors in the form of verdict used and remanded the case for a new trial.

MAN IMPERSONATING PHYSICIAN SENTENCED TO FIFTEEN-YEAR PRISON TERM FOR GRAND LARCENY

Re: State of Minnesota vs. Raymond Thayer Lawton

On February 8, 1956, Raymond Thayer Lawton, forty-six, formerly of White Bear Lake, Minnesota, was sentenced to a term of fifteen years in the State Prison at Stillwater, Minnesota, by the Hon. Axel B. Anderson, Judge of the District Court, at Faribault, Minnesota. Lawton had been tried and found guilty by a Rice County jury on January 25, 1955, of grand larceny in the second degree. However, the defendant was not sentenced at that time because he entered a plea of not guilty when arraigned on an information charging him with four prior convictions for felonies. While Lawton was awaiting trial on this charge, he escaped from the

LABORATORY MEDICINE

The day seems to be passing in which the physician performs much of his own laboratory work. Important as it may be to the diagnosis and management of disease, he will expect others to perform this role. He will come to rely increasingly on the skill of these other hands. This becomes clear when one considers the large contributions that chemistry, bacteriology, hematology, and other laboratory sciences are making to the advance of American medicine in this century.

A physician is by nature a skeptical person. A report from the laboratory may be to him just a slip of paper of questionable value. Still he must come to trust the skills of laboratory workers in order that these skills may help him make the decisions he must make. For this reason, if for no other, each physician and all physicians must be vitally concerned with the establishment of high standards of laboratory training and practice.

There are now many workers poorly trained; there are many schools that exploit heartlessly the needs for workers in this field. Glowing advertisements promise a short pleasure course, immediate vocational success. At the same time, approved schools of medical technology suffer progressive decrements in enrollment. Perhaps this field needs a sober study such as the one which culminated in the Flexner report on medical education in the early part of this century. After that report, organized medicine developed and enforced high standards of medical education, closing the "diploma mills." Today, medical technology, an emerging profession under the aegis of organized medicine, needs its strenuous support and encouragement. Under the best of circumstances, it will gradually fill the need for professional clinical laboratory workers.

In a further attempt to alleviate the shortage of adequately trained personnel, a course for laboratory workers at a sub-professional level was established at the University of Minnesota two years ago. This was established and developed with the cooperation and aid of the Minnesota State Medical Association, the Minnesota Hospital Association, the Minnesota Societies of Clinical Pathology and Medical Technology, and the Minnesota Department of Health. It is a one-year course with six months of formal training at the University and six months of internship in an approved hospital laboratory. The graduates of this course, called Laboratory Aides, will help to provide the need for workers especially in hospitals in smaller communities and in doctors' offices.

Modern medicine requires a larger laboratory participation in patient management than ever before. The physician is not physically able to perform all these laboratory functions himself. To meet this challenge, medical technology arose as an ancillary profession and with the support of organized medicine and of each individual physician will continue to play a steadily more effective role. There are needs for well-trained workers at a lower level such as laboratory aides. Finally, physicians themselves specializing in this field of endeavor will give it new orientation, force, and effectiveness.

—Harold S. Diehl, *Dean*

Minnesota State Medical Association

103rd Annual Meeting

Rochester, Minnesota—May 21-23, 1956

Preliminary Program

BUSINESS SESSIONS

Kahler Hotel

SATURDAY, MAY 19

2:00 P.M.—Council............University Club, East Room
6:00 P.M.—Council............University Club, East Room

SUNDAY, MAY 20

8:30 A.M.—Council............University Club, East Room
10:00 A.M.—Reference Committees....Mezzanine Floor
2:00 P.M.—House of Delegates....Royal Coach Room
6:00 P.M.—Council............University Club, East Room
8:00 P.M.—House of Delegates....Royal Coach Room

MONDAY, MAY 21

8:30 A.M.—Council............University Club, East Room
12:15 P.M.—House of Delegates......Royal Coach Room
12:15 P.M.—Committee on Medical Testimony Room to be assigned

TUESDAY, MAY 22

8:30 A.M.—Council............University Club, East Room
8:30 A.M.—Committee Breakfasts Rooms to be assigned

WEDNESDAY, MAY 23

8:30 A.M.—Council............University Club, East Room
8:30 A.M.—Committee Breakfasts Rooms to be assigned

SOCIAL EVENTS

SUNDAY, MAY 20

5:30 P.M.—Fellowship Hour for Officers, Councilors, Delegates—Mezzanine Floor, Kahler Hotel.
6:00 P.M.—Smorgasbord, open to all. Rochester Country Club.

MONDAY, MAY 21

Luncheons

12:00 noon—American Medical Women's Association, Minnesota Branch. Town House.
12:15 P.M.—Minnesota Society of Clinical Pathologists. Town House.
5:00 P.M.—Fellowship Hour. Cloud Room. Kahler Hotel.

Dinners

6:15 P.M.—Minnesota Academy of General Practice. Elizabethan Room, Kahler Hotel.
6:30 P.M.—Minnesota Society of Clinical Pathologists. Annual dinner and business meeting. Regency Room, Kahler Hotel.
7:00 P.M.—Minnesota Radiological Society. Centennial Room, Kahler Hotel.

Open House

9:00 P.M.—Minnesota State Medical Association. Mayo Civic Auditorium.

TUESDAY, MAY 22

5:45 P.M.—President's Reception. Cloud Room, Kahler Hotel.

Dinner

7:00 P.M.—Minnesota State Medical Association, Annual Banquet, Elizabethan Room, Kahler Hotel.

ROUND TABLES

Kahler Hotel—12:15 P.M.

MONDAY, MAY 21

Disturbed Clotting Mechanism in Obstetrics
John A. Haugen, Minneapolis
Charles A. Owen, Rochester
Office Gynecology ....M. B. Sinykin, Minneapolis
Management of Head Injuries
Winchell McK. Craig, Rochester
Palliative Treatment for Metatastic Carcinoma of the Breast ....William M. McConahey, Rochester
David G. Decker, Rochester
Fluid and Electrolyte Balance
Edmund B. Flink, Minneapolis
Management of Hypertension ....James J. Coll, Duluth

TUESDAY, MAY 22

Recent Trends in Antibiotic Therapy
Donald R. Nichols, Rochester
Diagnosis and Management of Rheumatic Fever
Paul F. Dwan, Minneapolis
Diarrheas in Infants and Children
Charles W. Rogers, Winona
Treatment of Overweight ....William B. Martin, Duluth
Controversial Issues in Myocardial Infarction and Cardiac Emergencies ....H. B. Burchell, Rochester
Diabetes ....Moses Barron, Minneapolis
Alterations in the Blood Levels During Gestation
W. J. McGanity, Assistant Professor of Obstetrics and Gynecology, Vanderbilt University School of Medicine, Nashville, Tennessee

WEDNESDAY, MAY 23

Peripheral Vascular Diseases (Excluding Hypertension) ....David M. Craig, St. Paul
Convulsive Disorders in Children
V. R. Zarling, Minneapolis

Treatment of Urinary Infections....E. N. Cook, Rochester

Allergic Reactions to Drugs
Louis E. Prickman, Rochester

Management of Asthma With and Without the Steroids ....Albert V. Stoesser, Minneapolis

Management of the Acutely Agitated Patient
Gordon R. Kamman, St. Paul

Present Status of Rh Sensitization
Emil G. Holmstrom, Professor and Head, Department of Obstetrics and Gynecology, University of Utah, Salt Lake City, Utah

GENERAL SESSION

Mayo Civic Auditorium

MONDAY, MAY 21

A.M. *Morning Session*

8:30 Visit Scientific and Technical Exhibits Auditorium

9:00 Closed Circuit Color Television.........Auditorium
Surgery of Biliary Tract Disease

Intermission

10:15 Visit Scientific and Technical Exhibits Auditorium

11:00 RUSSELL D. CARMAN MEMORIAL LECTURE
"New Techniques in Cholecystography"
L. Henry Garland, Clinical Professor of Radiology, Stanford University Medical School, San Francisco, California

11:30 ARTHUR H. SANFORD MEMORIAL LECTURE
"Metabolic Relationship of Potassium, Nitrogen and Sodium"
Paul R. Cannon, Professor of Pathology and Chairman, Department of Pathology, University of Chicago, Chicago, Illinois

P.M.

12:15 Miscellaneous Luncheons
Round Table Luncheons

Afternoon Session

1:30 Visit Scientific and Technical Exhibits Auditorium

2:00 Closed Circuit Color Television.........Auditorium
The Technique of Proctoscopy and Office Procedures

Intermission

3:15 Visit Scientific and Technical Exhibits Auditorium

4:00 "Neoplasms of the Terminal Portion of the Colon"
John R. Hill, Rochester

4:30 MINNESOTA DIVISION, AMERICAN CANCER SOCIETY LECTURE
"Endocrine Influences in the Treatment of Cancer"
Charles Huggins, Professor of Surgery and Director of the Ben May Laboratory for Cancer Research, University of Chicago, Chicago, Illinois

5:15 Obstetric Manikin Demonstration ....Stage
W. J. McGanity, Vanderbilt University

5:15 Visit Scientific and Technical Exhibits Auditorium

6:00 Special Dinners

9:00 Open House....................Mayo Civic Auditorium

GENERAL SESSION

Mayo Civic Auditorium

TUESDAY, MAY 22

Morning Session

A.M.

8:30 Visit Scientific and Technical Exhibits Auditorium

9:00 Closed Circuit Color Television..........Auditorium
The Clinical Use of Cortisone and Related Hormones

Intermission

10:15 Visit Scientific and Technical Exhibits Auditorium

11:00 MINNESOTA HEART ASSOCIATION LECTURE
"Diagnosis and Treatment of Subacute Bacterial Endocarditis"
J. Scott Butterworth, Associate Professor of Medicine, New York University Post-Graduate Medical School, New York

11:30 NORTHWESTERN PEDIATRIC SOCIETY LECTURE
"The Changing Character of Infections as the Result of the Era of Chemotherapy"
Franklin H. Top, Professor and Head, Department of Hygiene and Preventive Medicine, State University of Iowa, Iowa City, Iowa

P.M.

12:15 Round Table Luncheons

Afternoon Session

1:30 Visit Scientific and Technical Exhibits Auditorium

2:00 Closed Circuit Color Television..........Auditorium
Orthopedic Surgery—The Painful Shoulder

Intermission

3:15 Visit Scientific and Technical Exhibits Auditorium

4:00 "Physical Medicine"
Miland E. Knapp, Minneapolis

4:30 MINNESOTA MEDICAL FOUNDATION LECTURE
"The Patient Who *Won't* Get Well"
Donald W. Hastings, Professor and Head, Department of Psychiatry and Neurology, University of Minnesota, Minneapolis

5:15 Obstetric Manikin Demonstration ....Stage
Emil G. Holmstrom, University of Utah

5:15 Visit Scientific and Technical Exhibits Auditorium

Evening Entertainment

7:00 ANNUAL BANQUET
Elizabethan Room, Kahler Hotel

GENERAL SESSION

Mayo Civic Auditorium

WEDNESDAY, MAY 23

Morning Session

A.M.
8:30 Visit Scientific and Technical Exhibits
Auditorium
9:00 Closed Circuit Color Television........Auditorium
Abnormal Uterine Bleeding

Intermission

10:15 Visit Scientific and Technical Exhibits
Auditorium
11:00 "The Importance of the Diagnosis of Glaucoma"
P. J. Leinfelder, Professor of Ophthalmology, College of Medicine, State University of Iowa, Iowa City, Iowa
11:30 "Industrial Noise, Every Physician's Problem"
K. M. Simonton, Rochester
P.M.
12:15 Round Table Luncheons

Afternoon Session

1:30 Visit Scientific and Technical Exhibits
Auditorium
2:00 Closed Circuit Color Television........Auditorium
Management of Common Skin Diseases
3:15 Medical Quiz
Frank Krusen, Rochester, Moderator

SPECIAL SESSIONS

MONDAY, MAY 21

Morning Session

A.M.
9:00 Minnesota Society of Clinical Pathologists—Annual Tumor Clinic
Judd Hall, Mayo Clinic, New Building
Moderator: Arthur P. Stout, M.D., New York City
11:30 ARTHUR H. SANFORD LECTURESHIP IN PATHOLOGY
"Metabolic Relationship of Potassium, Nitrogen and Sodium."
Paul R. Cannon, Professor of Pathology and Chairman, Department of Pathology, University of Chicago, Chicago, Illinois
P.M.
12:15 Luncheon ....Town House

Afternoon Session

2:00 Tumor Clinic (continued)
Judd Hall, Mayo Clinic, New Building
6:00 Annual Dinner and Business Meeting
Regency Room, Kahler Hotel

WEDNESDAY, MAY 23

P.M.
2:00 Minnesota Academy of Ophthalmology and Otolaryngology..............Mayo Foundation House

"Criteria for Cataract Extraction"
P. J. Leinfelder, Associate Professor of Ophthalmology, College of Medicine, State University of Iowa, Iowa City, Iowa

"Divergence Insufficiency"
T. G. Martens, Rochester

"Retinal Artery Pressures in the Diagnosis of Intracranial Vascular Disease"
R. W. Hollenhorst, Rochester

"Otitic Hydrocephalus"
J. B. McBean, Rochester

"Carcinoma of the Nose and Sinuses"
K. D. Devine, Rochester

"Sudden Deafness of Obscure Origin"
O. E. Hallberg, Rochester

Mayo Civic Auditorium

History of Medicine in Minnesota

THE MEDICAL HISTORY OF RICE COUNTY
(1855-1901)

ADOLPH M. HANSON, M.D.
Faribault, Minnesota

(Continued from January issue)

Faulkner, Lloyd Anson.—Was born in Faribault, September 30, 1862; attended public school there, then went to Shattuck. He studied medicine in Chicago and graduated from Bennett Eclectic Medical College in 1885. He was licensed in Minnesota in the same year (June 6) and started to practice in St. Paul. In 1895 he practiced in Duluth and from about 1898 to 1905 in Good Thunder. In 1909, or before, he located in Lonsdale. About 1914 he returned to St. Paul. Dr. Faulkner was an active Mason, reaching the 32nd degree. He was an ardent collector of curios, especially Indian relics and geological specimens.

He died December 18, 1933, in St. Paul, survived by his widow, Anna, and five children: Lloyd, who became head of the *St. Paul Dispatch* art department; J. F. Faulkner; Mrs. Ernest Ritter of St. Paul; Mrs. F. Armstrong of Minneapolis and Lester Faulkner of Chicago.

Gadbois, Wilfred.—He graduated from the Medical School of the University of Victoria, Canada, in 1887. He was granted his Minnesota medical license on May 11, 1887, and first established his practice in Faribault where he stayed through 1898. He died on January 18, 1912, in Montreal.

Gibson, W. C. (Wm. C.).—Was listed in Faribault in 1890. He was licensed in Minnesota "by examination" December 10, 1886. It is not known exactly when he came to Faribault. In 1895 and 1898 he is listed in Morristown and from 1903 through 1909 in Seattle, Washington. He died on June 8, 1915, at his home in Port Angeles, Washington, at the age of fifty-two.

Goudy.—A Dr. Goudy opened an office in Dundas on August 2, 1876. A local weekly of that date made the following announcement:

> "Dr. Goudy from Illinois has hung out a shingle at R. C. Snyder's where he is prepared to deal out physic to suffering humanity. Dundas is pretty well supplied with M.D.'s at present, there being three practicing physicians here just now."

He was not licensed and nothing more is known about him.

Goulet, John B. A. (also **John** and **J. A. B.**).—Graduated from Victoria College, Montreal, Canada in 1883. He was licensed in Minnesota on March 21, 1885, and in the same year he established his office and residence in Faribault at Third and Elm Streets. He stayed in Faribault only a short time and apparently died before 1890.

Greaves, William.—Practiced in Northfield from 1890 apparently until his death there on June 23, 1907. Dr. Greaves was born in Ontario November 17, 1842, and moved with his parents to Cannon Falls, Minnesota, in 1856. He graduated from the Medical School of the University of Michigan in 1870 or 1871 and was licensed in Minnesota on October 11, 1883.

Hitchcock, Harvey A.—He settled in Springfield, Brown County, Minnesota, in 1878. Born in Courtland County, New York, he studied medicine with a preceptor in Janesville, Wisconsin, and attended a Medical Institute in Cincinnati, Ohio. He removed from Janesville, Wisconsin, to establish a practice at Morristown, Minnesota, and departed Morristown for California in 1881.

Hubbard, E. E.—A graduate of the Minneapolis College of Physicians and Surgeons, he practiced [presumably in Minneapolis] immediately following his graduation in 1894 until 1896, when he went to Faribault where he practiced for two years before moving to Kansas City. There he eventually became the professor of pathology at the Medical Clinic College.

Hunt, William Augustus.—Practiced in Northfield from at least 1890 through 1909. He apparently was born in Northfield in 1858; graduated from the University of Michigan Medical School in 1882 and was licensed in Minnesota December 31, 1883. He was a member of the Minnesota State Medical Association and at one time its third vice president. Dr. Hunt, a gentleman of the "old school," was highly respected and loved in Northfield. He died on January 27, 1921 at Northfield.

Hutchinson, Henry.—A homeopath, practiced in Northfield for four years, 1874 to 1878. He was born in Montreal, Canada, August 20, 1849, and came to Northfield with his parents in 1858. It is said that he started his medical studies under the preceptorship of Dr. A. P. Skeels of Northfield and then went to the Hahnemann Medical College, Philadelphia, from which he graduated in 1874; he started to practice in Northfield in the same year. His Minnesota license he received January 17, 1884. After four years in Northfield Dr. Hutchinson moved to St. Paul in 1878 where in the early 90's he was on the homeopathic board of physicians and surgeons of St. Luke's Hospital. In 1884 he was president of the Minnesota State Homeopathic Institute. From 1901 to 1910 he was president of the State Board of Health and he held a professorship in the Minnesota Homeopathic Medical College. He died in Algiers, Africa, on December 1, 1910.

Huxley, Fredrick R.—A graduate of the Medical School of the University of Minnesota, and now in his eighty-first year and still in active practice here in Faribault where he started his practice in the year 1901, is now the grand old man of our medical profession in Rice County, Minnesota. What Nathan Marvin Bemis was to our profession in his day, Fred Huxley is to it now in our more modern day. A conscientious and highly ethical practitioner all his life and with diagnostic abilities far above the average, even to this date (December 8, 1954), particularly in relation to a correct interpretation of skiagraphs, he is highly respected by all who have the privilege of knowing him. A widower for years and with his two sons middle-aged, he still is active in his office and hospital practice.

He started his practice in Faribault after completing his residency at the Minnesota State School for the Feeble-Minded and Epileptics, and has practiced in Faribault for 54 years.

Jackson, Roscoe Neely.—Settled in Faribault in 1883. He was born in Boonville, N. Y., July 7, 1856. He graduated from the Hungerford Collegiate Institute in 1877 and from the Long Island College and Hospital in 1880.

At a conference called by Dr. H. M. Bracken, secretary of the Minnesota Board of Health, in the office of Dr. Daniel M. Cool during an epidemic of small pox in Faribault, which Dr. Jackson had stubbornly persisted in diagnosing as "Cuban itch," and not small pox at all, Dr. Bracken listened to the arguments, pro and con, for several hours. Getting weary of the long drawn-out discussion and wanting to retire for the night, he suddenly interrupted it by saying:

"Gentlemen! You will *diagnose* this as *small pox*. You will *treat* it as *small pox*. You will *quarantine* it as *small pox*. Or *I* will quarantine your town."

(Told the writer by F. R. Huxley, M.D., of Faribault).

Dr. Jackson established a big practice in Faribault. He had one of the first automobiles—an open single-seat White Steamer with the boiler under the seat, which made the seat too hot for comfort. So Jackson had a stovepipe attached to the compartment under the seat that rose perpendicularly back of it above his head. This outlandish engine scared all the horses in the town and in the country all-around. Everybody knew who Dr. Jackson was. He moved to California when about ready to retire. There he was drowned with a sister-in-law when his automobile went off a bridge into deep water.

Jonson, Norton.—Apparently practiced in Canon City around 1870. Dr. Adelia E. Hutchkiss (Sanderson) a pioneer practitioner in Osakis (Todd and Douglas Counties), supposedly started her medical education in his office.

Juell, N.—This medical doctor came to Red Wing, Goodhue County, in 1893, following postgraduate study in Germany. He had previously practiced in Wisconsin and in Minnesota. He was a member of the Goodhue County Pension Board. In 1897 he moved to Faribault where he practiced medicine and ran a drug store.‡

Kelley, Lewis Halsey.—Physician and journalist, was born in Ovid, Seneca County, New York, on October 3, 1808. He graduated from Geneva Medical College in 1838 and Albany Medical College in 1840. Dr. Kelley came to Minnesota in 1858. He was a respected physician and surgeon at Rochester, Minnesota, from 1857 to 1863. He was also a newspaperman from 1860 up to the time of his death in August, 1872 in Owatonna. He bought the *Rochester City News* in 1860 and changed its name to the *Rochester Republican,* becoming its local editor in 1861 and selling it in 1863. He then moved his printer's equipment to Owatonna where he established that town's first newspaper, the *Plain Dealer*. In 1868 he moved to Northfield and took on the *Northfield Recorder* and, a little later, the *Northfield Enterprise*. In 1870 he moved to Faribault to become the publisher of the *Faribault Leader*. Following his death two years later, a son carried on in his father's place, and a grandson after him.§ (While this gentleman does not rightly belong to a medical history of Rice County, Minnesota, he was a medical man, retired or not, with a high degree of civic consciousness, interested in the welfare of Faribault and so an inspiration to other members of the profession).

Knight, George H.—A graduate of the Medical School of the University of New York City in 1881. He received his Minnesota license on October 13, 1883, and established his practice at Faribault where he was a highly respected member of the medical profession. He stayed there until at least 1890. Between 1895 and 1905 he was in Lakeville, Conn.

---

‡He may be identical with Dr. Niles (also Nils or Nieles) R. H. Juell (or Jewell), a graduate from Rush Medical College who practiced in Becker County in the late 1880's, who was licensed in Minnesota in 1885 and practiced in Goodhue County in the middle 1890's and in Swift County around 1903 and 1905, and who moved to California around 1904.

§See "Medicine and Its Practitioners in Olmsted County Prior to 1901" by Nora H. Guthrey, MINNESOTA MEDICINE, 1949-1951.

Lang.—A Dr. Lang was a partner of Martin L. Mayland for a short time—so short a time, in fact, that his only memory here in Faribault is no more than a faint memory of his surname. Dr. Mayland practiced in Faribault from 1893 to 1937.

Lawrens, Lambert.—His professional card which appeared in the *Faribault Republican* in 1887 read:

> "Lambert Lawrence,
> Physician and Surgeon.
> Office next to Dr. Dale's
> in Theopold block. Speaks
> English, French*, and German."

No other information about him is available.

Leighton, L. W.—This M.D. came to Faribault in the late summer of 1855 or 1856, and vanished like a gentle unnoticed summer's breeze. He opened an office opposite the Brunswick Hotel, but, like the King's men, he marched to the assault and marched right back again.

Lynde, Cornelius V.—Homeopath. Graduate of the Hahnemann Medical College and Hospital of Chicago in 1880 or 1883. He was born in the State of Vermont in the year 1858. He was licensed to practice medicine in Minnesota in 1886 and came Faribault from West Concord, Dodge County, in 1890. He had practiced in other Minnesota towns and villages: Medford, Parkers Prairie, et cetera. He died in a diabetic coma in the Owatonna Hospital on November 27, 1926, as another of those tragic cases of a physician who failed to heal himself. At Faribault he bought the practice of Dr. T. W. Roberts and became his successor. He must have thought that he bought a lemon and learned the bitter lesson that one cannot purchase the confidence of patients with filthy lucre, but must earn it by one's own merit, when he threw it all overboard several years later, perhaps himself already a diabetic and with that handicap, without being aware of it.

Martinez, St. V.—This medical man moved to Northfield from Rochester, Minnesota, in 1879. In 1893 he was practicing in Cedar Rapids, Iowa. He wrote at that time to a friend that he was practicing in that state under the "Time Act" of that state, and that he had been appointed an "Official Counsel of the World's Congress." In 1896 he was listed in a four-state medical directory as a resident of Cedar Rapids, Iowa. His name is not in the 1st edition of the AMA Directory (1906), or later. He was born in Bohemia and arrived in Minnesota in the 1870's. He lived for a few months in Steele County. His professional card in a Rochester newspaper in August of 1874 describes him as an "eclectic physician." He paid a visit to Europe in 1878.

Mattocks, Brewer.—Came to Faribault in 1881 and was still there in 1886 when he had his residence and office at the Corner of Cedar and Hickory Streets.

Dr. Mattocks, one of Minnesota's outstanding physicians, was born in Keeseville, New York on September 12, 1841. He came to St. Paul with his father in 1856. In

---

*As late as the year 1912, approximately one-fourth of the population of Faribault was made up of immigrants from the Canadian Province of Quebec and/or their descendants. They spoke Old French, saying, *vad couche* for *allez couche,* and *il fait fret* for *il fait froid,* et cetera.

1861 he graduated from the Philadelphia College of Pharmacy and in 1864 from a medical college in St. Louis. Between 1861 and 1865 he served in the Civil War as hospital steward and as assistant surgeon. In 1865 he started to practice in St. Paul and continued until 1881. He was one of the founders of the Ramsey County Medical Society in 1870, was on the faculty of the St. Paul School for Medical Instruction (1872) and was very active in the affairs of the Minnesota State Medical Society.

From Faribault he moved to Pittsburgh, Pennsylvania and he retired in 1900. Dr. Mattocks had a fine education and he published a number of poems. He died at the Old Soldiers' Home in the Twin Cities in 1934.

Mayland, Lewis L.—He took care of the practice of his brother, Dr. Martin L. Mayland, while his elder brother, three years his senior was absent from Faribault during the summer of 1896. He was born October 13, 1871, at Kenyon, Minnesota. Before commencing the study of medicine he taught school for two years in northern Minnesota. He graduated in 1896 from the Medical School of the University of Minnesota. He may have stayed with his brother for a while before moving to Hayfield. In 1899 he moved to Red Wing and in 1902 to Bagley, Minnesota. In 1910 he left Minnesota for Chester, Montana, and established himself in Great Falls in 1913. He died in 1942.

Mayland, Martin Lars.—Was born on September 23, 1868, on a farm at Aspelund, Goodhue County, Minnesota, to the Scandinavian immigrants and pioneer settlers Lars A. and Unna Thorsness Mayland. He attended Goodhue County public schools and Carleton College of Northfield. His medical training he received at the Medical School of the University of Minnesota from which he graduated in 1892. During the years at the University he spent all his spare time at weekends and during summer vacation with Dr. Edouard O. Boeckmann of St. Paul and often assisted the latter in his surgical work. He was licensed shortly after his graduation and he started to practice in Mankato. After only a year there he moved to Faribault to establish himself permanently.

Avid for further training, he graduated from the Post-Graduate Medical School of New York in 1893 and took an intensive course of six weeks in operative surgery at McGill University, Montreal, in 1895.

When he arrived in Faribault he had an unsually complete set of surgical instruments for that time, a team of horses, a buggy, a good fur coat and one thousand dollars. There he found a number of physicians, but no hospital. Being a surgeon at heart and of a not too healthy constitution he sorely missed the hospital and he became instrumental in the founding in 1895 of the Hunter Hospital in Faribault—ironically almost adjoining the cemetery on the western outskirts of the town. There he performed the first operation and did most of the surgery during its existence of eleven years. It was closed in 1906.

It was at this hospital that he met Josephine Olivette Sullivan. Miss Sullivan had graduated from the Minneapolis General Hospital Training School for Nurses in March, 1901, and only a few days later became supervisor of the Hunter Hospital. They were married on November 30 of the same year. She continued to assist him as nurse and anesthetist especially during the period of more than two years between the closing of Hunter Hospital and the opening of St. Luke's Hospital on May 16, 1909, when all surgery had to be carried out in homes. His and his nurse's painstaking care in preparing a room for operation and his meticulous surgical procedures resulted in healing by primary intention of all his clean cases during this period —and there were over 300 operations, mostly of a major type.

Dr. Mayland practiced surgery in Rice County for over forty-four years. He had a suave and pleasingly dignified personality, was sympathetic, kindly, but firm and uncompromising when occasion demanded it. He died on November 16, 1937, in his seventieth year in a Rochester Hospital of Hodgkin's Disease. He was survived by his wife, a son, Martin L. Mayland of St. Louis, Kentucky; his brother, Dr. Lewis L. Mayland of Great Falls, Montana; and two sisters. The Maylands had lost one daughter.

Dr. Mayland had been prominent in civic and political affairs. During his last twenty-five years he served three terms as county coroner; he held this position for six years prior to his death. For several years he was city health officer of Faribault. His work in the establishment of Hunter Hospital has been mentioned; he also took an active part in the establishment of St. Luke's Hospital. During World War I he was a member of the volunteer service corps; he was drafted and prepared for active service when the war ended. He was a member of the Rice County Medical Society, the Southern Minnesota Medical Association, the Minnesota State Medical Association and the American Medical Association. Dr. Mayland was an active member of the Congregational Church and was exalted ruler of the Faribault Lodge B.P.O.E.

Morbeck, Zacharias.—This medical man was listed as practicing the healing art in Northfield in 1893. He was not licensed in Minnesota and nothing more is known about him.

Nelson, Louis F.—Graduate of the Medical School of the University of Maryland in 1849. Licensed to practice in Minnesota on November 12, 1883. He, too, was one of many, who came to Faribault and went on, again, like a ghost ship passing in the night.

Nichols (or **Nicholas**), **B.**—A homeopath. He was one of the sixteen signers of the articles of the Association of the Minnesota State Homeopathic Institute at the Globe Hotel in St. Paul in 1867. He settled in St. Paul in 1852. He moved to Northfield in 1853 and later became a physician to the Minnesota Institute for the Education of the Deaf, Dumb and Blind, which opened in Faribault in 1863. He was elected president of the Minnesota State Homeopathic Association in 1873. He was reported as practicing in Portland, Oregon, in 1882.

Orcutt, Isaac Hall (also **I. H. Orcutt** and **Hall Orcutt**).—He came to Northfield in 1896 and stayed there until his death in 1912. This part of his life was spent doing research on Alcohol and Tobacco, and lecturing about them to the Women's Temperance Union in various towns in Minnesota and Iowa. He served on the Town School Board of Northfield for several years and was engaged in overseeing certain properties of his own in various parts of the State. He died in Northfield on October 7, 1912, in his sixty-sixth year, of Bright's disease, survived by his second wife (the first had died in 1884), a son and a daughter. He was buried in Oaklawn Cemetery, Northfield.

Dr. Orcutt was born on June 7, 1847, near Westmoreland, Oneida County, in the State of New York. In 1866 he studied at Groveland Seminary at Wasioja. Then he taught in the school of his boyhood in Concord Township. It seems that he started the study of medicine with a private physician as preceptor but then went to the Chicago Medical College from which he graduated on March 21, 1876. Immediately he began to practice in Byron, Olmsted County. In April, 1879, he left to take a course of natural sciences at the University of Pennsylvania and received a degree of doctor of philosophy before he returned to his practice in June, 1880. Poor health caused him to restrict his medical work to office practice and early in 1883 he retired to a farm. In 1884 he moved to the Dakota Territory, where after two years of medical practice he was appointed professor of natural sciences at the Dakota Agricultural College, also as college physician. It seems it was during these periods that his special interest in ill effects of alcohol and tobacco on the nervous system developed. In 1893 he moved to Owatonna where in the following year he published a small book, *Microbes and Men*. As mentioned, in 1896 he moved to Northfield.**

Pentz, F. C. F.—Born in Hanover, Germany, on January 20, 1823. He received an education at the high school, and in 1841-1842 served in the Prussian army. In 1846, he entered Göttingen Medical Institute, but did not take a full course. He returned to the Prussian army in 1848. He came to the United States in 1850. In 1855 he married Miss Rebecca Abbott, a native of Indiana. One year later he removed to Minnesota, but did not settle permanently in the state until the year 1867. The History of Rice County (1882) goes on to state: "Mr. Pentz has practiced as a physician part of the time since coming to this country." He was in Northfield from 1881 to 1882.

Phillips, John Rutledge.—Practiced in Northfield for over twenty years—until one year before his death. He graduated from the Medical School of the University of Victoria, Montreal, Canada, in 1884 and came to Minnesota in the same year, where he was licensed on November 10. He first practiced in Dundas and moved to Northfield in the early 1890's. Because of illness he left Northfield about a year before his death. The last six months he spent at the Presbyterian Hospital in Chicago suffering from a heart condition. He died on September 2, 1912. He was representative, in 1909, in the Legislature.

For fifteen years he served on the United States Pension Examining Board in Northfield. He was a member of all Masonic Lodges, the Knights Templars and Osman Temple of St. Paul.

It is said that Dr. Phillips came to Dundas completely without funds—all he had was his medicine bag. At first he walked for miles to visit his patients, but after a while secured snowshoes. Later he made calls on horseback and finally was able to have a horse and buggy. He was known as a genial man, beloved by his patients and friends. When he moved to Northfield he soon was a successful physician. Dr. Philips never married.

In 1906 he was joined in Northfield by his nephew, Dr. John Gilbert Phillips. The latter was born at Drumbo, Ontario, January 7, 1877, and came to the United States at the age of 11 with his parents who settled in Marlette, Michigan. He graduated from Northwestern University in 1905. After about a year with the Lenont Clinic at Virginia he came to Northfield to join his uncle. This association lasted several years. Dr. John Gilbert Phillips practiced a total of about sixteen years in Northfield and died there November 22, 1922, at the age of forty-five. His widow, Nellie W. Phillips, still lives in Northfield (1955).

Pillsbury, Charles.—He was the homeopath partner of Dr. D. H. Roberts of Owatonna in 1898. He came from Duluth, where he had practiced for eleven years. He practiced in Faribault (1898-1900) and then returned to Duluth.

(To be continued in the July issue)

Meetings and Announcements

MEDICAL MEETINGS

State

MINNESOTA STATE MEDICAL ASSOCIATION, annual meeting, Mayo Civic Auditorium, Rochester, May 21-23, 1956.

Northwest Pediatric Society, spring meeting, Rochester, May 22, in conjunction with meeting of Minnesota State Medical Association. Secretary, Dr. T. C. Papermaster, Minneapolis.

National

American Association of Blood Banks, ninth annual meeting, Somerset Hotel, Boston, Massachusetts, September 3-5. Secretary Marjorie Saunders, 725 Doctors Building, 3707 Gaston Ave., Dallas, Texas.

American Cancer Society and National Cancer Institute, Third National Cancer Conference, Sheraton-Cadllac Hotel, Detroit, Michigan. June 4-6. Write National Cancer Conferences Coordinator, American Cancer Society, 521 West 57th Street, New York 19, New York.

American College of Physicians, 37th annual session, Los Angeles, California, April 16-20.

American Ophthalmological Society, Hot Springs, Virginia, May 31 to June 2.

Medical Library Association, fifty-fifth annual meeting, Hotel Statler, Los Angeles, California, June 18-22. Write Mrs. Ella Crandall, Libraian, Los Angeles, County General Hospital, 1200 North State Street, Los Angeles 33, California.

Microbiological Institute, ninth annual meeting, Department of Biological Sciences, Purdue University, Lafayette, Indiana, June 4-9. Write Division of Adult Education, Engineering Administration Building, Purdue University, Lafayette, Indiana.

Symposium for General Practitioners on Tuberculosis and Other Chronic Pulmonary Diseases, fifth annual meeting, Saranac Lake, New York, July 7-13. Dr. Edward N. Packard, general chairman, Symposium for General Practitioners, P.O. Box 262, Saranac Lake, New York.

Third National Cancer Conference, Detroit, Michigan, une 4-6.

International Meetings

Canadian Medical Association, Quebec, Canada, June 10-14. Secretary, Dr. Arthur D. Kelly, 150 St. George St., Toronto, Ontario, Canada.

Congress of International Society of Hematology, Hotel Somerset, Boston, Massachusetts, August 27 to September 1. Secretary, Dr. W. C. Maloney, 39 Bay State Road, Boston, Massachusetts.

Inter-American Congress of Cardiology, Havana, Cuba, November 4-10. Write Dr. Ramon Aixala, Apartado 2108, Havana, Cuba.

International Congress of Clinical Chemistry, Hotel New Yorker, New York, September 9-14. Secretary, John G. Reinhold, 711 Maloney Building, University of Pennsylvania, Philadelphia 4, Pennsylvania.

World Medical Association, Havana, Cuba, October 9-15. Secretary, Dr. Louis H. Bauer, 345 E. 46th St., New York 17, New York

Pan American Congress on Cancer Cytology, Miami, Florida, January 8-12, 1957. Dr. J. Ernest Ayre, chairman, 1155 N. W. 14th St., Miami, Florida.

European Congress of Cardiology, Stockholm, Sweden, September 10-14. Dr. Karl E. Grewin, secretary, Sodersjukhuset, Stockholm, Sweden.

International Congress on Diseases of the Chest, Cologne, Germany, August 19-23. Murray Kornfeld, executive director, 112 East Chestnut St., Chicago 11, Illinois.

International Congress of Gastroenterology, London, England, July 18-21. Herman Taylor, secretary, London Hospital, White Chapel, London E. 1, England.

International Congress of Internal Medicine, Madrid, Spain, September 19-23. Dr. J. C. DeOya, secretary, No. 90, Madrid, Spain.

International Congress of Radiology, Mexico, D. F., Mexico, July 22-28. Dr. Jose Noriega, secretary, Tepic 126 (2 e piso), Mexico, D. F. 7, Mexico.

International Congress of World Confederation for Physical Therapy, Statler Hotel, New York, New York, June 17-23 Mildred Elson, American Physical Therapy Association, 1790 Broadway, New York 19, New York.

MINNESOTA ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY

The Minnesota Academy of Ophthalmology and Otolaryngology adopted the following resolution at its February meeting in Saint Paul with respect to professional association between optometrists and physicians:

"The Minnesota Academy of Ophthalmology and Otolaryngology is officially opposed to the professional association of optometrists and physicians practicing in this state; and that a copy of such official action be placed in the hands of every member of the Minnesota State Medical Association.

"The term 'professional association' indicates the joint office practice of a physician and optometrist for the purpose of diagnosing or treating eye diseases; and (or) the examination for, or prescribing of, eye glasses."

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

Principal speaker at a meeting of the Minnesota Society of Neurology and Psychiatry in St. Paul on March 13 was Dr. Irving C. Bernstein, who presented an inaugural thesis entitled, "Psychiatric Aspects of Dysmenorrhea." The paper was discussed by Dr. John L. McKelvey.

MEDICLINICS OF MINNESOTA

Mediclinics of Minnesota, a clinical lecture course, was held at Fort Lauderdale, Florida. from March 5 to 14. Lectures and panel discussions were presented every weekday morning and late afternoon. Members of the faculty for the course included Dr. Harold F. Buchstein, Dr. Harry B. Hall, Dr. Arthur C. Kerkhof, Dr. Ames W. Naslund, Dr. O. L. Norman Nelson, Dr. Owen F. Robbins, Dr Albert V. Stoesser, Dr. Robert J. Tenner, Dr. Richard L. Varco and Dr. Edgar A. Webb.

ST. PAUL SURGICAL SOCIETY

The St. Paul Surgical Society will meet at the Minnesota Club, St. Paul, on April 18, with dinner at 6:00 p.m. and scientific session at 8:00 p.m. Dr. John McLean will discuss "The Conservation of Ovarian Tissue."

MINNEAPOLIS SURGICAL SOCIETY

The next meeting of the Minneapolis Surgical Society will be held at the Calhoun Beach Hotel on May 3, with dinner at 6:00 and scientific session at 8:00 p.m. Principal speaker will be Dr. Ernest Lampe of Cornell University.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

Applications for certification by the American Board of Obstetrics and Gynecology for the 1957 Part I examinations are now being accepted. Application for re-examination, as well as requests for resubmission of case abstracts, must be made before October 1, 1956. All communications should be sent to the secretary, Dr.

CRIPPLED CHILDREN SERVICES SPRING CLINIC SCHEDULE

The Crippled Children Services spring clinics are now being held at various cities in Minnesota. Clinics have been held at Cloquet, Grand Rapids, St. Cloud, Albert Lea, Hibbing and Faribault. Forthcoming clinics are listed below:

**Gaylord	April 25	Le Sueur, Brown, Nicollet, Carver, Scott, McLeod, Sibley
*Worthington	April 28	Cottonwood, Nobles, Jackson, Pipestone, Murray, Rock
*Detroit Lakes	May 5	Becker, Mahnomen, Clay
*Thief River Falls	May 12	Kittson, Red Lake, Marshall, Roseau, Pennington
**International Falls	May 18	Koochiching, Lake O'Woods
*Brainerd	May 26	Crow Wing, Wadena
*Morris	June 2	Bigstone, Pope, Douglas, Stevens, Grant, Traverse

*County Welfare Board Social Service for clinic intake arranged by Field Representative. All *new* patients are requested to bring written referrals from their family physician.

**Social problems arising at clinic will be referred to County Welfare Board on day of clinic. In-take service *not* necessary from County Welfare Board. New patients are requested to bring written referrals from their family physicians. *All* patients should have appointments arranged through local Public Health Nurses.

Note: Gillette State Hospital patients will not be attending *any* orthopedic field clinics.

CONTINUATION COURSES AT THE UNIVERSITY OF MINNESOTA CENTER FOR CONTINUATION STUDY

Dates		
May 7-12	Electrocardiography for General Physicians	Dr. Harold Levine Harvard University Medical School
May 14-19	Proctocology for General Physicians	
May 24-26	Surgery for Surgeons	Dr. Robert M. Zollinger Ohio State University College of Medicine
June 4-6	Dermatology for General Physicians	

Woman's Auxiliary

N AREA PLAN

Irs. L. R. Boies

A large and growing auxiliary presents problems which ust be recognized. The membership of the Auxiliary the Hennepin County Medical Society has experienced rapid growth in the past few years, but the attendance meetings and group participation in our activities mains fairly constant. An appraisal of the situation d re-evaluation of the Auxiliary's intent is imperative.

One objective which we must constantly keep in sight this: to accomplish what we plan requires the en- usiasm and support of every individual member—in er lies the life of our organization. She must be mind- l of her membership, which is unique. Our program a broad one, and we want every member to feel that e is an important cog in a community group of omen banded together to further the ideals of a highly spected profession—medicine.

Present-day problems must be recognized, also. Young- women, our leaders tomorrow, are finding permanent elp in the home almost a legend of the past. As a sult, activity outside the home that offers them what ey want takes priority. Traffic problems and con- ested parking problems have eliminated late afternoon eetings. The trend is toward morning or mid-day atherings.

With these facts in mind, and with the added prob- m of a rapidly growing organization where we find urselves at meetings in a sea of unknown faces, we ave devised what we hope is a workable plan. It has mitless potentialities if carefully directed.

At the beginning of our year, the Auxiliary to the ennepin County Medical Society inaugurated the area lan, dividing its membership into small groups accord- g to the neighborhood in which each member lives. In is way, individuals experience a more personal rela- onship with other members and become better acquaint- d. From the organizational point of view, the large, nwieldy group becomes more manageable and there a closer contact with each member.

This idea is not a new one; it has proven successful n two occasions. In the spring of 1941, our benefit r fund raising was operated successfully under such plan. In the fall of 1953, it was used for simultaneous vil defense meetings. Echoes of "let's have more of ese friendly, intimate gatherings" were heard.

Since the groundwork for the plan was available om this earlier civil defense experience, the same oundaries for the areas have been maintained. Because e had followed the same pattern, it was very simple correlate auxiliary civil defense work with that of e Medical Society Civil Defense Co-ordinator, Dr. Carl . Waldron, for whom we are doing a project.

The Auxiliary has been divided and combined into n groups. Where the medical population was sparse, everal zones were combined, but each part has kept s identity. Each group has a chairman directly responsible to the area chairman who is a member of the Board of Directors. When a new member joins the Auxiliary, her name is sent to the area chairman who then places her in her respective group. A close follow-up by the group chairman becomes a welcoming gesture.

A purposeful goal is a prerequisite in any undertaking. This year's area projects have been to complete questionnaires on every member in the Auxiliary and to promote closer human relationships among physicians' wives. The latter was done by having simultaneous morning "Kafe Klatsches" in each area on our regular meeting day in January. The clamorous enthusiasm for more of these gatherings gave proof of this successful venture.

Representation according to areas has been worked out on the Hospitality and Fund Raising Committees. Incorporating the Telephone Committee into the area organization would have been extremely beneficial. The area designation for each member in our yearboook would also be most advantageous.

This earnest endeavor to further friendliness, understanding and "oneness" gives to a very large membership that feeling experienced in smaller auxiliaries.

REPORT ON MID-WINTER BOARD MEETING

Mrs. L. J. Leonard

The Mid-Winter Board meeting, held at the Minnesota Club in Saint Paul, Thursday, February 9, at 10:00 a.m., was called to order by Auxiliary President Mrs. H. H. Fesler. Following roll call and reports of officers and regional advisors, committee chairmen brought out many interesting statistics and suggestions.

Mrs. M. I. Hauge, chairman of Allied Medical Careers, has available an interesting new book for use of future nurses' clubs. She feels these clubs need sponsors to further acquaint them with facts pertaining to the profession.

Mrs. P. J. Pankratz, of Mountain Lake, announced that she and Dr. Pankratz are leaving Minnesota in April for a four-year assignment in Formosa, where he will have charge of a hospital. Goodbyes were said with a tinge of sadness, as she has been a loyal worker and her absence will certainly be felt. Auxiliary members wish them God-speed in their new undertaking.

Legislation offers many challenges, according to Mrs. Philip Arzt of Saint Paul. Members should particularly keep informed on H.R. 7225, regarding amendments to the Social Security Act, and the Jenkins-Keough Bill. To be well informed on legislative matters, members are urged to read the *Bulletin,* which contains current authentic data. Also reference to the column on Medical Economics in the February issue of MINNESOTA MEDICINE will prove beneficial.

Mrs. E. S. Mariette, Wayzata, urged that the auxiliary co-sponsor Mental Health Week, April 29 to

May 5. Therapy for the patient and a better understanding of the patient's problem can completely change the picture, as it did in the state of Kansas, but money has to be spent before it can be saved: an educational program is being promoted for this purpose. The assembly voted to co-sponsor this program along with the Junior Association of Commerce and the Federation of Women's Clubs.

Mrs. W. T. Greenfield, Cokato, stated that a list had been compiled of the various medicines desirable for shipping: this will be a great help to the chairmen assembling surplus drugs which they have collected from the doctors' offices. She also has a list of agencies and foreign hospitals, where these supplies are needed, and it is available to anyone desiring it.

Mrs. L. P. Howell, Rochester, gave a stimulating synopsis of the convention of presidents and presidents-elect in Chicago. She recommended reading in full Dr. Ernest B. Howard's speech to this assembly, a copy of which may be found in the January *Bulletin*.

Every auxiliary is requested to sponsor one safety program a year. Mrs. Charles Merkert, Minneapolis, suggested co-operating with the national auxiliary in promoting its new project "Gems" (Good Emergency Mother Substitute). A new series titled "Baby Time," which concerns baby sitters, will be seen on KSTP-TV on Tuesday and Thursday at one o'clock. She also recommended a new booklet, "You're in Charge," for distribution where needed.

American Medical Education Week will be April 22 to 29, according to Mrs. John Dordal, Sacred Heart. She suggested memorials and "In appreciation" cards to help swell this fund. A new book, "Face Facts," and a new film, "Danger at the Source," are both recommended as aids to a better understanding of this matter.

A new mental health kit, available through the AMA for 50 cents, should be in the hands of every auxiliary chairman, is the opinion of Mrs. William Gjerde of Lake City. She also suggested that members endeavor to work with local Chamber of Commerce groups when presenting programs to interest lay people.

It was a pleasure to see Mrs. William Ferguson, Walnut Grove, new president of the Lyon-Lincoln Auxiliary. Her secretary is Mrs. R. R. Remberg, Tracy. Congratulations to this newly formed auxiliary.

County presidents had items of interest to report. Mrs. F. T. Becker, Duluth, reported earning $400 at a rummage sale. The St. Louis County Auxiliary also sponsored a Glaucoma Detection Day. Mrs. Andrew Sinamark, Hibbing, said the Iron Range Auxiliary periodically gives awards to nurses during training upon completion of a specified number of hours of service. Mrs. Karl Walfred, St. Cloud, reported that more than 100 junior and senior high school girls from Foley, Cold Spring, and St. Cloud attended their nurse recruitment tea on February 7, which included a hospital tour, a panel discussion and showing of the film, "Nurses in White."

Dr. James Rogers Fox, radio and television director for the Minnesota State Medical Association, spoke on "The Doctor's Place in the Community." Polls show doctors at the top of the list as far as individual esteem is concerned, though they do not always occupy this position from a financial standpoint and by the amount of community work they do. It is much more difficult to attain a medical degree today than it was ten years ago, and the average age before a graduate entering a specialty field is ready to practice is thirty. Doctors generally err by not entering into public activity; they should live in a total society, not just in the office and the hospital.

Mr. Harold Brunn, assistant executive secretary of the State Medical Association, spoke on the American Medical Education Foundation, and said there were eighty-one approved medical schools, private and public, in the country. Ten million dollars is needed annually to supplement the income the Foundation now has. The new "Eighty Dimes" promotion for AMEF should not be a door-to-door canvas; contributions should be solicited only within one's own family and medical group. Always check with your county society before taking action on any matter and be sure that it is approved by the Council.

The Rochester Auxiliary invited all Auxiliary members to attend the State Convention in that city, May 21 to 23. The national convention will be in Chicago, June 11 to 13.

A special thank-you to the hostesses for the day—Mrs. Wallace Ritchie and Mrs. J. R. Meade, both of Saint Paul, who were in charge of arrangements.

The Food and Drug Administration has announced that the evidence of record does not warrant removal of the hypnotic drugs acetyl carbromal and bromural from the list of drugs required by federal law to bear the label statement: "Warning: May be Habit Forming."

This decision was made on the basis of evidence received at public hearings held on June 7 and September 13, 1955. A summary of the evidence and a proposed order have been published in the Federal Register. Interested persons who appeared at the hearings are privileged to file exceptions to the tentative order with specific references to the pages of the transcript of testimony or to exhibits on which the exceptions are based.

In Memoriam

FREDERICK GAY CARTER

Dr. Frederick G. Carter, superintendent of Ancker Hospital, Saint Paul, from 1924 to 1935, died February 19, 1956, in Cleveland. He was sixty-seven years of age.

Dr. Carter served as president of the Minnesota Hospital Association and the American College of Hospital Administrators. He was a member of the Ramsey County Medical Society and the Minnesota State Medical Association.

He became administrator of Christ Hospital in Cincinnati after leaving Ancker, and in 1939 he went to St. Luke's Hospital in Cleveland.

EDWARD A. COLP

Dr. Edward A. Colp, a physician in Robbinsdale, Minnesota, for twenty-eight years, died February 10, 1956, while vacationing on the gulf coast aboard the *S.S. Monarch of the Seas.* He was fifty-five years old.

A native of Fargo, North Dakota, Dr. Colp graduated from Tufts Medical School, Boston, Massachusetts.

He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association, the American Medical Association and Phi Chi medical fraternity.

Dr. Colp served as a commander in the Navy during World War II.

Surviving are his wife, Hazel A.; a son, Richard Kolling, Minneapolis; a daughter, Mrs. Robert Corrigan, Northfield, Minnesota; his stepmother, Mrs. Utta Colp, Miami, Florida; a brother, Donald Gray, Jr., Tucson, Arizona; a sister, Mrs. Robert D. Chellis, Weston, Massachusetts, and a stepsister, Mrs. Donald G. Burch, Saint Paul.

ALLAN FRANCIS GIESEN

Dr. Allan F. Giesen, physician and surgeon of Starbuck, died January 26, 1956, in Minneapolis. He was ifty-two years old.

Born in Groton, South Dakota, Dr. Giesen settled in Starbuck after graduating from the medical school of he University of Minnesota and served his internship at Ancker Hospital, Saint Paul, and Detroit Receiving Hospital.

Dr. Giesen was a member of the West Central Minneota Medical Society, the Minnesota State Medical Association, the American Medical Association, and Alpha Omega Alpha and Phi Chi medical fraternities.

He was very active in community affairs as a member of the Starbuck Commercial Club, chairman of the Pope County Republican Committee, and chairman of the chool board. He served on the Village Council and as mayor in 1934-35.

During World War II, he attained the rank of Commander in the U. S. Navy, seeing action in both the European and Pacific theatres. He was active in both he American Legion and the Veterans of Foreign Wars.

Dr. Giesen is survived by his wife; three sons, John, Philip, and Allan; three daughters, Allene, Toni and Kathi; his brother Earl, Delano; and his sister, Gertrude Giesen, Brigham City, Utah.

WALTER N. LEE

Dr. Walter N. Lee, Madison, Minnesota, physician for thirty-five years, died January 28, 1956, in Claremont, California. He was sixty-eight years old.

A native of Minneota, Minnesota, Dr. Lee graduated from the University of Illinois College of Physicians and Surgeons, and practiced from 1909 until 1914 in Mayville, N. D. He then moved to Madison, remaining there until 1949. At that time the family moved to California.

Dr. Lee was a veteran of World War I and was a member of the American Legion post in Madison. He was a member of the Madison Masonic lodge and of the Scottish Rite in Minneapolis. He was also a member of the Camp Release County Medical Society and the Minnesota State Medical Association.

Survivors include his wife; a daughter, Mrs. J. L. Armstrong, Cincinnati Ohio, and three sisters.

BERT G. LEVIN

Dr. Bert G. Levin, Saint Paul eye, ear, nose and throat specialist, died February 9, 1956. He had been with the Earl Clinic for twenty-eight years.

Dr. Levin was born at St. James, Minnesota, in 1899. He graduated from the medical school of the University of Minnesota in 1924 and interned at Minneapolis General Hospital. He was a member of the staff at Midway and Mounds Park Hospitals.

A member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association, Dr. Levin was also a fellow of the American College of Surgeons and a member of the American Academy of Otolaryngology.

Dr. Levin was on the board of Mount Zion Temple and was a past president of B'nai B'rith.

He is survived by his wife; two daughters, Susan and Jane; two brothers, Dr. Alfred Levin of Miami and David Levin of Grand Rapids, Michigan, and a sister, Mrs. Isadore Simon of Birmingham, Alabama.

DAVID POTEK

Dr. David Potek, Minneapolis, died January 11, 1956. He was fifty-one years old.

At the time of his death, Dr. Potek was on the staff of the Cambridge State Hospital, Cambridge, Minnesota. He was previously on the staff of the Glen Lake Sanatorium at Oak Terrace.

Born in Brailov, Russia, Dr. Potek graduated from the University of Minnesota medical school. He practiced medicine at International Falls, Minnesota, for a number of years and served with the army medical corps during World War II.

He was a member of the East Central Minnesota Medical Society and the Minnesota State Medical Association.

Survivors include his wife, Lillian; a daughter, Louise, and two sons, Arnold S. and Jason.

GEORGE E. SENKLER

Dr. George Senkler, Saint Paul physician for more than fifty years, died February 4, 1956. He was eighty-six years old.

Born in St. Cloud, Dr. Senkler attended the University of Minnesota and the University of Pennsylvania. He was a partner in the Miller Clinic and was associated many years with St. Luke's Hospital.

He was a member of the Ramsey County Medical Society and a life member of the Minnesota State Medical Association. He was also a "Fifty Club" member.

Mrs. Abigail Senkler, his wife; Mrs. J. Fuller Brown of Newport News, Virginia, his daughter, and seven grandchildren are survivors.

WALTER HERMAN UDE

Dr. Walter H. Ude, Minneapolis radiologist, died of a heart attack February 10, 1956, while he and Mrs. Ude were vacationing in Hawaii. He was fifty-nine years old.

A native Minnesotan, born in Vernon City in 1896, Dr. Ude graduated from the University of Minnesota. He interned and studied roentgenology at Minneapolis General Hospital. He had practiced in Minneapolis for thirty years, and was senior partner in the firm of Ude, Borman, Ahern and Stone.

Dr. Ude was a clinical professor of radiology at the University of Minnesota medical school. Recently, he was elected vice president of the Radiological Society of North America.

Dr. Ude was an active member of the Minnesota State Medical Association, serving in the House of Delegates and as a member of the Committee on Tuberculosis. He belonged to the Hennepin County Medical Society, the American Medical Association, the American Roentgen Ray Society, the American College of Radiology and Alpha Omega Alpha, honorary medical fraternity.

He was a diplomate of the American Board of Radiology, a veteran of World War I, a member of the Minneapolis Club and the Thirteen Club.

Survivors include his wife, Valborg; two brothers, August, Minneapolis, and Arthur, Saint Paul; and three sisters, Mrs. Anne Peterson, Spring Valley, Minnesota, Mrs. Doris Tonsing, Dallas, Texas, and Mrs. Clara Halsey, Terrell, Texas.

IRVING GEORGE WILTROUT

Dr. Irving G. Wiltrout, born November 22, 1885, in Hudson, Wisconsin, died February 1, 1956, in Oslo, Minnesota, where he began his practice in 1920.

Dr. Wiltrout studied medicine at the Wisconsin College of Physicians and Surgeons and practiced in Swanville, Minnesota, for a few years before serving in the medical corps during World War I.

Dr. Wiltrout was prominent as a civic leader in Oslo, serving as mayor and as a member of the Board of Education. He was area health officer and was the Marshall County Draft Board Medical Officer. He was instrumental in building the Oslo War Museum and spent much time directing the exhibits.

He was a member of the Red River Valley County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Wiltrout is survived by his wife; two daughters, Mrs. Robert Dryden of Atlanta, Georgia, and Mrs. James Ritchie, Chicago, Illinois; a sister, Florence Wiltrout, Chippewa Falls, Wisconsin, and two grandchildren.

Burial was at Fort Snelling National Cemetery in Minneapolis.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

(Continued from Page 245)

Rice County Jail on May 19, 1955, and was not apprehended until July 16, 1955, when he was arrested in Minneapolis. Lawton was therefore also charged with the crime of escape from jail and on February 8, 1956, he entered a plea of guilty to this charge and also to the information charging him with having four prior convictions for felonies. For the crime of escape the defendant was sentenced by Judge Anderson to a term of three years in the Minnesota State Prison, the sentence to run concurrently with the fifteen-year sentence.

In the grand larceny case, the defendant was charged with issuing without funds a $50.00 check on or about August 31, 1954, which he signed "R. Thayer Lawton, M.D., White Bear Lake," and representing that he was a doctor of medicine to a Faribault man, who cashed the check. It was alleged that the defendant knew at that time that he was not a doctor of medicine and that he had no funds on deposit at the bank. After he escaped from jail in Faribault, Lawton continued to represent himself as a doctor of medicine under an assumed name in Minneapolis. On July 14, 1955, it was reported to the Minnesota State Board of Medical Examiners that a "Dr. Jones," falsely representing himself as a teacher in pathology at the University of Minnesota, had issued two checks in Minneapolis without funds for a total of $25,025.00. When "Dr. Jones" was apprehended two days later in Minneapolis he proved to be Lawton. Lawton has no medical training and is not licensed to practice any form of healing in Minnesota.

Lawton has two prior convictions for felonies in the District Court of Hennepin County as follows: On January 7, 1926, he was convicted of forgery and sentenced to a term of not to exceed 5 years in the State Prison at Stillwater. He was sentenced on March 16, 1949, to an indeterminate term of not to exceed 7 years in the same institution on a grand larceny charge. The defendant was also convicted on March 24, 1928, in Federal District Court in St. Paul of forging an endorsement of a United States obligation and sentenced to 10 years in the United States Penitentiary at Leavenworth. Ten years later, on March 7, 1938, Lawton was convicted of grand larceny in the District Court at Libby, Montana, at which time he was sentenced to 2 years in Deer Lodge Penitentiary, Deer Lodge, Montana

General Interest

Dr. Robert A. Good, American Legion heart research professor at the University of Minnesota, spoke on "Progress in Heart Research" at a meeting of chairmen of the Twin Cities Heart Sunday in Minneapolis on February 11.

* * *

Dr. Allan J. Blake has been elected chief-of-staff of Doctors Memorial Hospital, Minneapolis. Named as associate chief of the medical staff was **Dr. R. H. Beiswanger**, with **Dr. Fred A. Rice** as secretary-treasurer.

* * *

At a meeting of the board of governors of the American Fracture Association in Chicago recently, **Dr. H. W. Meyerding**, Rochester, was elected permanent honorary president of the organization. Dr. Meyerding helped to organize the group several years ago and served as its president for the past three terms. He also was recently renamed U. S. delegate and chairman of the national committee of the International Society of Orthopedic Surgery and Traumatology, which he helped to found in 1929.

* * *

Dr. J. S. Blumenthal, clinical associate professor of medicine and chief of the allergy clinics at the University of Minnesota, presented a talk on allergy at a continuation course for the Clinical Dietetics Institute on March 1.

* * *

Dr. Frank G. Hedenstrom, who retired from service with the Child Health Clinic in St. Paul at the start of the year, was honored February 8 at the annual meeting in St. Paul of the Family Nursing Service. **Mrs. John C. Parish**, president of the group, presented Dr. Hedenstrom with a plaque in recognition of his services to the clinic, with which he was associated for thirty years.

* * *

Dedication ceremonies for **St. John's Hospital** at Browerville were held on February 26. The ceremonies were conducted by Bishop Peter W. Bartholome of St. Cloud. The hospital will be operated under the auspices of the Sisters of St. Benedict, Crookston.

* * *

Dr. Robert N. Barr, secretary and executive officer of the Minnesota Department of Health, presented a talk at a general staff meeting at the Rochester Health Center on February 23.

* * *

On the program at a sectional meeting of the American College of Surgeons in Colorado Springs, Colorado, March 5 to 7, was **Dr. H. Waltman Walters**, Rochester, who discussed operative and postoperative cholangiography.

* * *

Dr. Cecil J. Watson, chief of internal medicine at the University of Minnesota, has been named president of the Minnesota chapter of the Arthritis and Rheumatism Foundation. He succeeds **Dr. Charles H. Slocumb**, Rochester, in the office. Dr. Slocumb was named vice president, and **Dr. John M. Wolff**, Duluth, was elected second vice president of the group. Consultant to the organization is **Dr. N. L. Gault, Jr.**, assistant dean of the University of Minnesota Medical School. **Dr. H. E. Drill**, Hopkins, is a member of the board of directors. Named to the medical and scientific board was **Dr. William Proffitt**, Minneapolis.

* * *

Dr. Catharine Corson West, Minneapolis, was mistress of ceremonies at the annual Founder's Day banquet of Epsilon chapter, Alpha Epsilon Iota, professional medical sorority, in St. Paul on February 23. The meeting was attended by about seventy-five women physicians and associate members, wives of University of Minnesota Medical School department heads.

Three Twin Cities surgeons participated in programs of a sectional meeting of the American College of Surgeons in Milwaukee, Wisconsin, February 27 to 29. **Dr. F. John Lewis**, Minneapolis, discussed low-temperature techniques in surgery, and **Dr. Donald J. Ferguson**, Minneapolis, spoke on problems of internal hemorrhage. **Dr. N. Logan Leven**, St. Paul, presented a paper on intestinal obstruction.

* * *

Dr. James Rogers Fox, Minneapolis, spoke on "The Doctor's Family in the Community" at a meeting of board members of the Woman's Auxiliary to the Minnesota State Medical Association in St. Paul early in February. Dr. Fox is radio and television director for the association.

* * *

The thirteenth annual session of the Central Surgical Association was held at Rochester February 23 to 25, with **Dr. Edward S. Judd, Jr.**, Rochester, as chairman of the local committee on arrangements. Assisting him in operation of the meeting were **Dr. John H. Grindlay**, **Dr. Deward O. Ferris**, **Dr. B. Marden Black** and **Dr. George A. Hallenbeck**, all of Rochester.

* * *

Dr. Ancel Keys, University of Minnesota physiologist, left on March 19 to accompany **Dr. Paul Dudley White**, heart consultant to the President, on a trip to Japan and Hawaii. The two, plus a team of research workers, planned to study cardiac and blood pressure differences between native Japanese and Japanese on Hawaii. They expected to spend about two weeks in each location.

* * *

The second in a series of medical information forums was held in Minneapolis on February 19 and in St. Paul on February 24. The topic for discussion at both of the public meetings was the so-called "miracle" drugs. Panel members at both meetings were **Dr. Wesley W. Spink** and **Dr. Donald W. Hastings** of the University of Minnesota. Also on the panel for the Minneapolis forum were **Dr. O. L. N. Nelson** and **Dr. Ephraim Cohen.** On the panel for the St. Paul meeting were **Dr. Herman Wolff** and **Dr. Ben Sommers.** The Minnesota Medical Foundation was the principal sponsor for the health forums. Co-sponsors were the county medical societies, city health departments and metropolitan newspapers.

* * *

Two emeritus members of the Mayo Clinic staff have been named to the international executive council of the International College of Surgeons. They are **Dr. Henry W. Meyerding,** who was elected vice chairman of the council, and **Dr. William C. MacCarty,** both of Rochester.

* * *

Dr. S. Marx White, Minneapolis, was the subject of a lengthy biographical feature article in the *Minneapolis Sunday Tribune* on February 26. The article described some of the many and varied activities carried out by Dr. White in both medical and community life. One of the early leaders in the development of the University of Minnesota Medical School, Dr. White has been professor emeritus at the school since 1942. He was one of the founders of the Nicollet Clinic in Minneapolis in 1921. He served on the Glen Lake Sanatorium commission for thirty-one years. He has received numerous awards for his community service. Now aged eighty-two, Dr. White was convalescing from an eye operation at the time the newspaper article appeared.

* * *

President-elect of the Hennepin County Medical Society is **Dr. Herman E. Drill,** Minneapolis, whose election was announced at a meeting of the society on February 6. He will succeed **Dr. Robert Priest** on October 1. Other officers elected include **Dr. Karl E. Sandt,** first vice president; **Dr. Wellington W. Rieke,** second vice president, and **Dr. Conrad J. Holmberg,** re-elected secretary-treasurer.

NEW LOCATIONS

Dr. A. J. Floersch, after practicing at Glencoe for the past two years, has become associated in practice with **Dr. John A. McIntyre** in Owatonna.

* * *

Dr. Samuel L. Hamilton, who recently completed postgraduate work in surgery and urology at the University of Illinois Research and Educational Hospital, Chicago, has become a member of the staff of the Interstate Clinic at Red Wing.

* * *

Dr. John J. Heimark, after completing a three-year fellowship in medicine at the Mayo Clinic, has joined the department of internal medicine of the Mankato Clinic, Mankato.

* * *

Dr. Paul Fraser, who recently finished a year of postgraduate training at St. Joseph Hospital, Pontiac, Michigan, has become a member of the Mork Clinic at Anoka.

* * *

Dr. Thomas W. Milroy, formerly of Winnipeg, Canada, has become associated with the Lenont-Peterson Clinic at Virginia, where he is specializing in obstetrics and gynecology.

* * *

Dr. William H. Rock, who formerly practiced in North Minneapolis, has become associated in practice with **Dr. R. H. Larson** in Anoka.

MINNESOTA BLUE SHIELD-BLUE CROSS

At a meeting of the Board of Directors on February 29, 1956, the Board decided to open Blue Shield enrollment to doctors for either Plan A or Plan B group contract. Prior to this time, in view of the courtesy care of a physician and his family by another doctor, offering Blue Shield contracts to doctors was considered unnecessary.

Within recent months an increasing number of Minnesota doctors have applied for Blue Shield contracts, and it has been found that many doctors consider Blue Shield coverage a method of solving some of the embarrassments arising in the courtesy care of one physician by another. It also has been learned that many other Blue Shield plans offer their contracts to doctors.

Several types of physician enrollment in groups are possible. These include group enrollment in clinic or doctor's office personnel groups, hospital staff groups, and in case no such groups are available, a general medical profession group into which individual applications of physicians will be funnelled.

A doctor who wishes to obtain a Blue Shield contract can secure one in any of the first three groups mentioned if such groups exist in his locality. If such group enrollment is not open to him, he can obtain an application blank by writing to Blue Cross-Blue Shield, 2610 University Avenue, Saint Paul 14, Minnesota.

During January, 1956, 86,829.5 days of hospital care were provided for 14,526 Blue Cross subscribers. Since 1933, approximately 11,600,000 days of hospital care have been provided for over 2,000,000 subscribers.

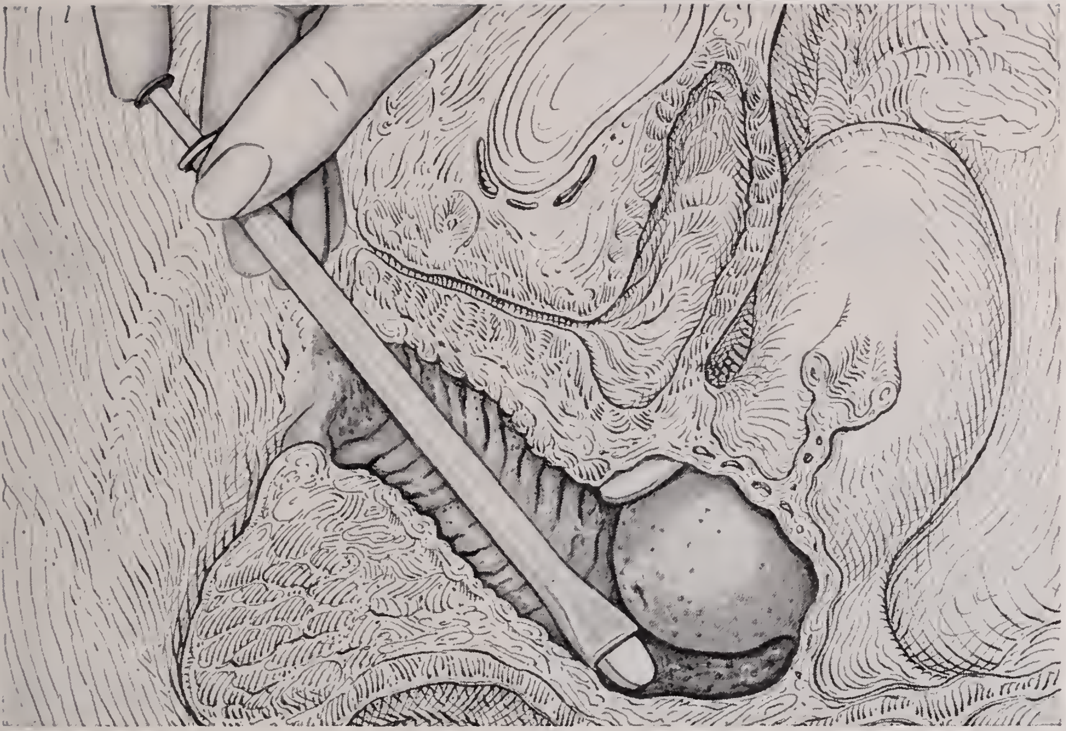
In comparing the first month of 1956 with the same period of the preceding year, it is noted that although the average length of stay remained at 6.0 days, the number of persons hospitalized increased 45 cases per year per 1,000 contracts protected.

The total number of Minnesotans protected by Blue Cross as of January 31, 1956, is 1,030,263 an increase of 3,295 persons since December 31, 1955.

Since the announcement of the availability of the new Blue Cross Optional Series Contracts in January of 1956, several outstate enrollment promotions have been completed. Initial announcement was made and a promotional campaign carried out in the St. Cloud area, January 9 to 16. The second outstate promotion announcing the availability of the Optional Series Contracts was carried out in the Madison, Minnesota area. Following in their respective order were: Brainerd, New Ulm and Faribault.

Similar promotions will be conducted in approximately 14 other outstate areas throughout 1956 in co-operation with the Hospital Administrator, medical staff and civic officials of the particular city or town.

FLORAQUIN® VAGINITIS REGIMEN



New Intravaginal Applicator for Improved Treatment of Vaginitis

The restorative treatment of vaginitis with Floraquin is now further improved by a new aid to tablet insertion. Faulty insertion is no longer a failure factor in therapy.

The new Floraquin applicator is designed for simplified insertion of Floraquin tablets by the patient. This plunger device, made of smooth unbreakable plastic, places the Floraquin tablets in the fornices and thus assures coating of the entire vaginal mucosa as the tablets disintegrate. The patient inserts two Floraquin tablets with the applicator in the morning and also two tablets at night, with treatment being continued through at least two menstrual periods. During menstruation it is desirable to increase medication to eight tablets daily to combat the alkalinity of the menstrual flow.

Warm acid douches (2 ounces of 5 per cent acetic acid or white vinegar to 2 quarts of warm water) may be taken as often as desired for hygienic purposes.

Floraquin contains Diodoquin® (diiodohydroxyquinoline, U.S.P.), the safe and effective protozoacide and fungicide. Lactose, anhydrous dextrose and boric acid are included to help restore the normal acid pH of the vaginal secretions. Such an acid vaginal medium then encourages the growth of normal flora and makes the environment unfavorable for pathogens.

A Floraquin applicator is supplied with each box of 50 (a new package size) Floraquin tablets. G. D. Searle & Co., Research in the Service of Medicine.

New Floraquin Applicator and commercial package of 50 Floraquin tablets available on request to . . . **SEARLE** P. O. Box 5110, B

Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

A COURSE IN PRACTICAL THERAPEUTICS- Third Edition. Martin Emil Rehfuss, M.D., F.A.C. LL.D.(Hon.). Professor of Clinical Medicin Emeritus, and Director of Division of Therapeutic Department of Medicine, Jefferson Medical Colleg Philadelphia; Attending Physician, Jefferson Medic College Hospital, Philadelphia; and Alison Ho Price, A.B., M.D., Associate Professor of Medicin Jefferson Medical College, Philadelphia; Assistant Ph sician to Jefferson Medical College Hospital, Philade phia; Chief Clinical Assistant, Diabetic Clinic, Cur Clinic, Philadelphia. 972 pages. Illus. Price $15.0 cloth. Baltimore: Williams & Wilkins Co., 1956.

YOUR BLOOD PRESSURE AND HOW TO LI WITH IT. William A. Brams, M.D. 160 pages. Illu Price $2.95, cloth. Philadelphia: J. B. Lippincott Co 1956.

NERVOUSNESS, INDIGESTION AND PAIN; Popula Edition. By Walter C. Alvarez, M.D. 235 pages. Ne York: Harper, 1954. Price $3.50.

Although no word such as *psychosomatic* that migh be outside the average layman's vocabulary appears i this edition, Dr. Alvarez stresses the effect of the em tions on the physical organs and their functioning. H quotes Maudsley's "The sorrow which has no vent i tears may make other organs weep," as well as man passages from Austen F. Riggs.

The content deals chiefly with differential diagnoses particularly techniques of distinguishing functional fro organic illnesses, the number of the former greatly exceeding that of the latter, especially in women patients he apparently feels that neuroses are limited to the fe male of the species. Because the mental origin of complaints is so often not recognized, many needless operations are undergone by patients who afterwards find thei symptoms unalleviated. Dr. Alvarez himself calls this a "different" kind of book, which "deals more with sick unhappy persons than with their diseases, more with symptoms and their meaning than with disease entities. . ."

Even to the point of being repetitious, he emphasizes the importance of the personal conference, in which the doctor becomes personally acquainted with the patient and gets the history of his illness directly from the patient himself. So important and enlightening is the history he says, that physicians would do well to trust the diagnosis made on the basis of the history in preference to a conflicting diagnosis arrived at from laboratory or x-ray reports. It naturally follows that if the conference is to result in a diagnosis, the physician is going to have to give the patient more time than is usually customary and he will have to be more attentive to and sincerely interested in the patient as a person. From this conference the physician should be able to "size up the patient," that is, to determine the degree of sensitivity of the patient—the sensitiveness of his digestive tract and of the involuntary nerves, the sensitiveness of the patient to ıin, his suggestibility to emotion, his intelligence and ill power, and even his sanity. In fact, he says the av- age internist would be surprised to know how many ildly insane persons go through his office each month. ?hysicians can detect these psychoses and neuroses by ıch little clues as the patient's exaggerated sensitivity light, his feeling that he is discriminated against, neg- cted, and unloved, the number of jobs he has held the past five years, the inability of the patient to sit ill . . ." Even careless grooming in a patient who has rmerly been meticulous in his appearance can suggest personality change or even an actual brain lesion.

The charge of repetitiousness might be applied to his anner of expression but not to his copious illustrative ses drawn from his own experience, each of which ives home a point. By means of these illustrations he es to "Keep young physicians from forgetting that ere is such an organ as brain, that it has many dis- ses all its own, and that the symptoms of some of ese appear first in the abdomen." Throughout the book pears his central thought expressed in such words as . . no sign of disease was found when the abdomen ıs explored, I suspect . . . the disease that caused the scomfort is up in the brain, from whence the distress projected out to the periphery . . ." and "Abdominal stress is a common initial symptom of neuroses, psy- oses, and other diseases of the brain."

Since most of the neuroses and psychoses are too mild r the patient to be sent to a psychiatrist, since there a dearth of well qualified psychiatrists anyway, and ıce the average patient cannot afford to pay for the any hours needed for psychiatric treatment, Dr. Alvarez lieves that the internist should have enough training the principles of psychiatry or psychotherapy to make ch referral unnecessary. He believes that an understand- g physician, without giving offense, can make clear to e patient "what can be done to change a bad environ- ent or to remove a handicap or to lessen the strain on m." Sometimes when a bad situation cannot be anged, the patient can be taught to recognize the istence of tensions and to realize that in cases where ner conflicts are unreasolvable the wiser source is to ırn to submit to the inevitable.

Though his emphasis is on the neurotic origin of the ajority of complaints and symptoms which come to a ctor's attention, he does admit that sometimes the pa- nt is suffering from organic rather than functional ness. In such cases, he states that "many symptoms thout identifiable causes are produced by little, rarely cognized strokes." B.M.

ANDBOOK OF PEDIATRICS. By Henry K. Silver, M.D., C. Henry Kempe, M.D., and Henry B. Bruyn, M.D. 548 pages. Illus. Price $3.00. Los Altos, California: Lange Medical Publications, 1955.

The many charts, tables and illustrations and the ırty-one well-organized chapters of this pocket-sized ndbook cover an amazing amount of information con- ely and in ready reference form. As a supplement to e standard pediatrics textbooks it would be useful to diatricians, general practitioners, medical students and ɔse cramming for Board examinations. It is worth the ree dollars it costs. M.C.

nonhormonal anti-arthritic

BUTAZOLIDIN®

(brand of phenylbutazone)

relieves pain • improves function • resolves inflammation

Employing the serum protein-polysaccharide ratio (PR) as an objective criterion of rheumatoid activity, it has again been shown that BUTAZOLIDIN "...produces more than a simple analgesic effect in rheumatoid arthritis."[1]

Clinically, the potency of BUTAZOLIDIN is reflected in the finding that 57.6 per cent of patients with rheumatoid arthritis respond to the extent of "remission" or "major improvement."[2]

Long-term study has now shown that the failure rate with BUTAZOLIDIN in rheumatoid arthritis, and particularly in rheumatoid spondylitis, is significantly lower than with hormonal therapy.[3]

All the benefits of prednisone and prednisolone plus positive antacid action to minimize gastric distress

Multiple Compressed Tablets of 'Co-Deltra' and 'Co-Hydeltra' are designed to help the physician cope with the problem of gastric distress which might otherwise become an obstacle to therapy with the newer steroids prednisone and prednisolone. Each Multiple Compressed Tablet is specifically formulated as a "tablet within a tablet" to provide stability and to release in sequence antacid and anti-inflammatory components.

New STEELINE Pediatric Table

Eases the burden of the physician's daily work

Includes built-in tare balance scale, built-in measuring rod, foam rubber cushion and electrical outlets with cord and plug—there are no accessories to buy. Top quality construction features include all-welded steel body, two roomy drawers and a large open compartment with shelf, providing easy, unhampered access to instruments and supplies. Front edge is protected from wear by a stainless steel baffle plate. Despite the fact that this new table has been designed to provide the physician with the best modern equipment, efficient modern production methods in our own factory permit us to keep the price well below that of comparable models. Write today for complete information.

The Bells Are Ringing

In cities, towns and villages all over America, the ringing of church bells one day in April will mark the launching of the annual Cancer Crusade of the American Cancer Society. At the same time, in many doctors' offices, the staccato ring of door and telephone bells will mark the success of a major objective of the Society.

"Fight Cancer with a Checkup" is the American Cancer Society's immediate, short-range answer to the terrible toll of lives taken each year by this dread disease. It is to your office that the Society is urging the public to go for the periodic examinations that can mean the early detection and prompt treatment of cancer, and could prevent thousands and thousands of needless deaths.

Achievement of our ultimate goal — the conquest of cancer — will be largely determined by the response to our plea to "Fight Cancer with a Check". This year the Society needs $26,000,000 to carry on its vital program of education, research and service.

"Fight Cancer with a Checkup and a Check"—a winning combination. With your support and the cooperation of the public, the sound of victory will one day ring through the land.

Fastest and shortest-acting oral barbiturate

'Seconal Sodium'

(SECOBARBITAL SODIUM, LILLY)

Among its many uses:

- Simple insomnia
- Unruly pediatric patients
- Obstetric patients
- Procedures associated with moderate pain

In 1/2, 3/4, and 1 1/2-grain pulvules and in ampoules, suppositories, and 'Enseals' (Timed Disintegrating Tablets, Lilly); also, Elixir 'Seconal' (Secobarbital, Lilly).

Lilly

good medicine
for
sick youngsters

Suspension Chloromycetin® Palmitate

pleasant-tasting Chloromycetin for pediatric use

Your young patients won't hit the war path at medication time when the prescription calls for SUSPENSION CHLOROMYCETIN PALMITATE. Its appealing custard flavor rates it as "good medicine" with the most rebellious braves.

Good medicine, too, for a wide variety of infections in infancy and childhood, CHLOROMYCETIN (chloramphenicol, Parke-Davis) affords rapid recovery and speedy convalescence.

Because of its liquid form, dosage of SUSPENSION CHLOROMYCETIN PALMITATE is easily adjusted. That it needs no refrigeration is an additional convenience to every harassed mother.

CHLOROMYCETIN

CHLOROMYCETIN is a potent therapeutic agent and, because certain blood dyscrasias have been associated with its administration, it should not be used indiscriminately or for minor infections. Furthermore, as with certain other drugs, adequate blood studies should be made when the patient requires prolonged or intermittent therapy.

supplied: SUSPENSION CHLOROMYCETIN PALMITATE, containing the equivalent of 125 mg. of Chloromycetin in each 4 cc., is available in 60-cc. vials.

about the

PROFESSIONAL CREDIT PROTECTIVE BUREAU

The Professional Credit Protective Bureau has proved very beneficial to many professional people who have adopted this excellent credit control and collection service.

We urge you to make use of this service since it will be of great benefit in recovering long delinquent accounts and in eliminating, through proper control measures, the accumulation of slow and bad accounts.

Professional Credit Protective Bureau
701 Metropolitan Bldg., Minneapolis 1, Minn.

YES, I would like to give the PROFESSIONAL CREDIT PROTECTIVE BUREAU a trial. Please ask one of their representatives to call on me without obligation to explain the plan in detail.

THE MILTOWN MOLECULE

the tranquilizer with
NO KNOWN CONTRA-INDICATIONS
ideal for prolonged therapy

- Effective in anxiety, tension and muscle spasm
- Well tolerated—not habit forming—essentially non-toxic
- Does not produce depression
- Orally effective within 30 minutes for a period of 6 hours
- Supplied in 400 mg. tablets. Usual dose: 1 or 2 tablets—3 times a day

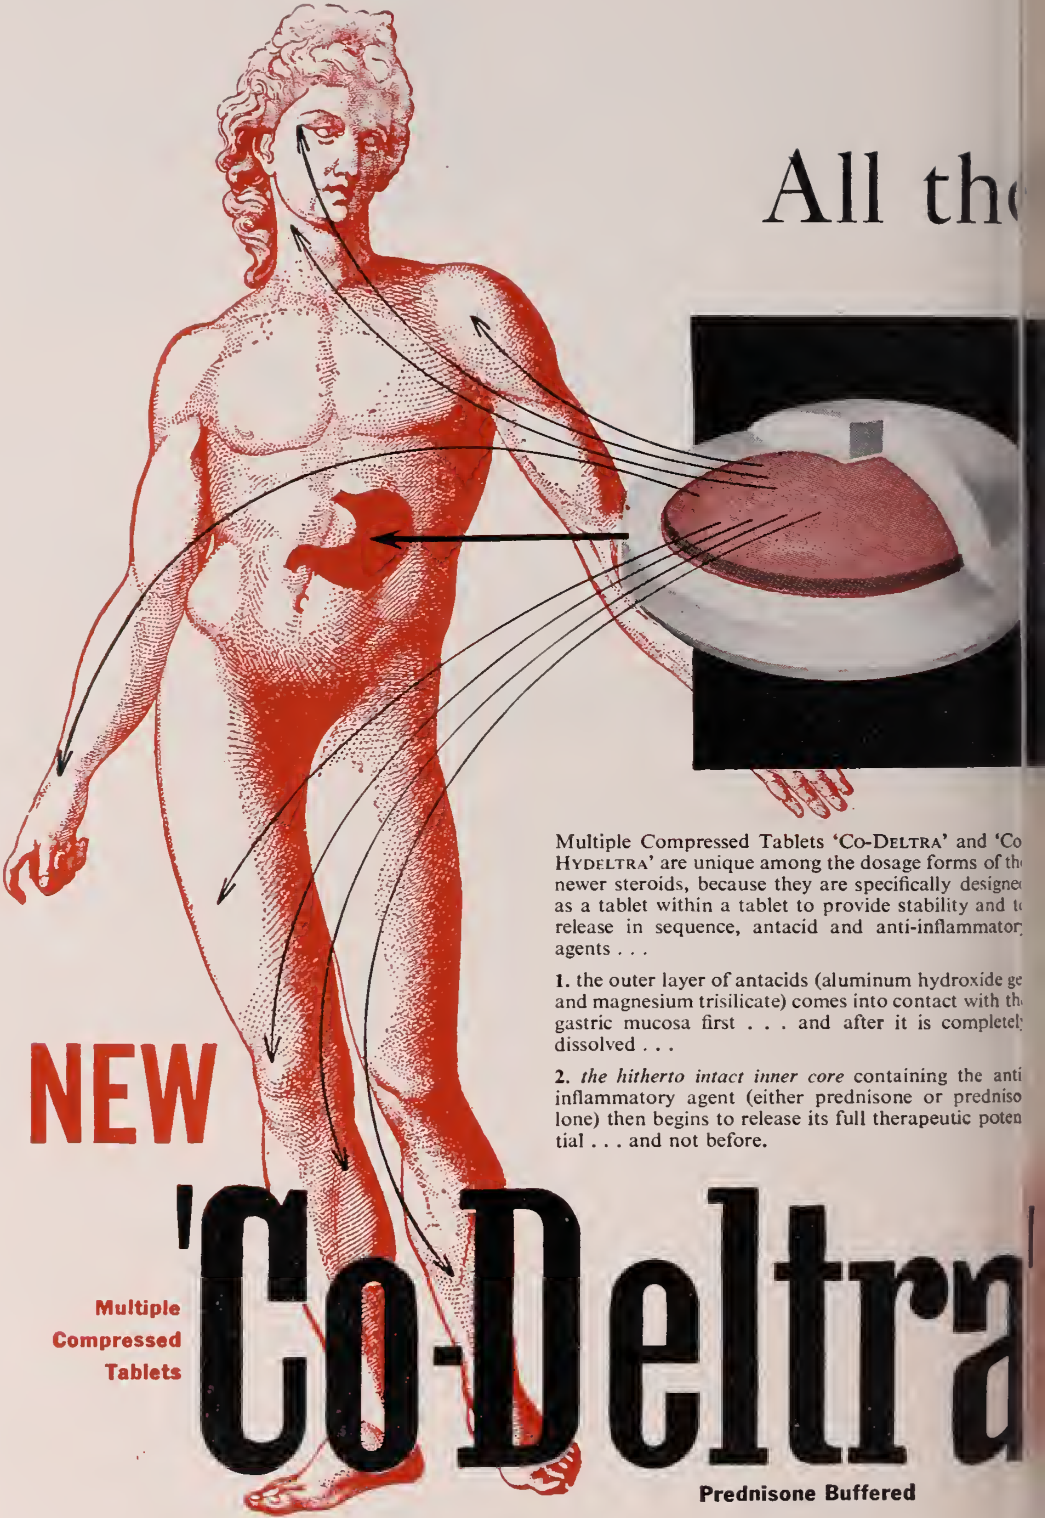
Miltown®

the original meprobamate—2-methyl-2-*n*-propyl-1,3-propanediol dicarbamate—U.S. Patent 2,724,720

DISCOVERED AND INTRODUCED by ***Wallace Laboratories, New Brunswick, N. J.***

Literature and Samples Available on Request

All th



Multiple Compressed Tablets 'Co-Deltra' and 'Co
Hydeltra' are unique among the dosage forms of th
newer steroids, because they are specifically designe
as a tablet within a tablet to provide stability and t
release in sequence, antacid and anti-inflammator
agents . . .

1. the outer layer of antacids (aluminum hydroxide ge
and magnesium trisilicate) comes into contact with th
gastric mucosa first . . . and after it is completel
dissolved . . .

2. *the hitherto intact inner core* containing the anti
inflammatory agent (either prednisone or predniso
lone) then begins to release its full therapeutic poten
tial . . . and not before.

NEW

Multiple
Compressed
Tablets

'Co-Deltra

Prednisone Buffered

benefits of prednisone and prednisolone plus positive antacid action to minimize gastric distress...

A reportedly higher incidence of gastric distress in patients receiving the newer steroids prednisone and prednisolone indicates the desirability of co-administering non-systemic antacids.[1]

To help the physician cope with this problem of gastric distress which might otherwise become an obstacle to therapy with the newer steroids . . . Multiple Compressed Tablets 'CO-DELTRA' (Prednisone Buffered) and 'CO-HYDELTRA' (Prednisolone Buffered) are now available.

'CO-DELTRA' and 'CO-HYDELTRA' are now available in bottles of 30 on your prescription. Each Multiple Compressed Tablet contains:

Prednisone or Prednisolone, 5 mg.; 300 mg. of dried aluminum hydroxide gel, U.S.P., and 50 mg. of magnesium trisilicate.

'CO-DELTRA' and 'CO-HYDELTRA'
are trade-marks of MERCK & CO., INC.

WASN'T THAT AN AWFUL PRICE TO PAY FOR MEDICINE?
MAYBE...BUT IT'S WORTH TWICE THAT MUCH TO GET WELL SO QUICKLY!
YES... THEY SAVED $900 AND MY USBAND'S LIFE!
IT DIDN'T COST THAT MUCH TO BE SICK WHEN I WAS A LITTLE GIRL!
OH, BUT ACTUALLY, SICKNESS COSTS LESS TODAY—AND MANY MORE CHILDREN GET WELL!
LIFE
POST

weeks' time lost away

…cture has changed.
…ulfa drugs . . . and
…umonia has stead-
…complicated cases
… And instead of
…ases, the doctor

…n deaths and

disability is the cut in the cost of curing pneumonia. More and more patients can now be cared for at home. As a result, the average case of pneumonia may cost no more than $100 . . . including loss of income, the doctor's visits and the "expensive" new medicines!

Today, more than ever before, an investment in prompt and proper medical care may well represent one of the biggest bargains of your life.

Makers of medicines since 1866

Back when today's adults were growing up, one out of every ten babies died before its first birthday. Now, advances in medical science are saving millions of young lives each year. Yet the cost of the better medical care available today is actually *less* than the best care you could get when you were a child!

The reason: new treatments and new medicines developed by the medical profession and the pharmaceutical industry.

A dramatic case in point is mastoiditis in children. Surgery was often able to save the child's life, but sometimes left him with a deaf ear. Nowadays, the doctor is often able to cure him with perhaps $25 worth of potent new medicines, and thus save the expense of an operation and hospital stay.

But most important, these new drugs are saving children's lives—by the millions. Once, the four most deadly child-killers were diphtheria, whooping cough, scarlet fever, and pneumonia. Nowadays, the number of deaths from all of these causes combined is actually less than the number of children killed by accidents.

And medical progress continues. Today, the dollar you spend for prompt and proper medical cure buys more than ever before—and may well represent one of the really extraordinary bargains of your life.

Makers of medic

The above advertisements appeared recently in Life, Saturday Evening Post, and Today's Health.

"How to look at a doctor's bill" could well serve as the title for recent Parke-Davis advertisements on the cost of medical care. For they suggest to the public new ways of looking at the extraordinary *value* one buys with each dollar spent for prompt and proper medical care.

These Parke-Davis messages talk in everyday language about familiar but "forgotten" facts. Some examples: the steadily decreasing cost of curing diseases such as pneumonia, the phenomenal reduction in the death-rate for children, the substantial savings in time and income because of the shortened duration of hospital stays.

By highlighting the heartening facts of medical progress in relation to the cost of medical care, this new series hopes to help in creating a healthy, realistic public opinion on the reasonableness of medical costs.

To do this successfully, we wish the facts to have the widest possible readership. Therefore these advertisements are being published regularly in such mass-circulation magazines as LIFE, the SATURDAY EVENING POST, and TODAY'S HEALTH.

If you would like to have folder-size reprints of any of these ads for your reception room, we will be happy to supply them on request.

DOCTORS EVERYWHERE NOW KNOW WHY

Viceroys Are Smoother

THE VICEROY TIP HAS . . .
TWICE AS MANY FILTERS

Professional men who have studied the microscopic analysis of the Viceroy filter now know why the Viceroy taste is smoother—never rough. Only Viceroy has 20,000 tiny filters in every tip—twice as many filters as the other two largest-selling filter brands. That is why Viceroys are smoother by far—never, never rough. That is why so many doctors now smoke and recommend Viceroys.

Yes, smoother taste because there are

TWICE AS MANY FILTERS IN EVERY VICEROY TIP

as the other two largest-selling filter brands!

how bioflavonoids with ascorbic acid help in threatened and habitual abortion...

Frequent nosebleeds, gum bleeding and easy bruising were observed in a high percentage of women who had repeated abortions, according to one study.[1]

Another investigator[2] reported abnormal capillary fragility in 80% of habitual aborters.

Bioflavonoids with ascorbic acid help to diminish abnormal capillary permeability and fragility by acting to maintain the integrity of the "cement" substance of capillary walls. Thus, C.V.P. may be a helpful adjunct in the management of threatened and habitual abortion.

C.V.P. provides the capillary-protectant factors of whole citrus bioflavonoid compound (sometimes referred to as "vitamin P complex"), combined with ascorbic acid. C.V.P. is water-soluble and believed to be more readily absorbed than relatively insoluble rutin.

CVP®

Each C.V.P. capsule or each teaspoonful (5 cc.) of syrup provides:

Citrus Flavonoid Compound . . .	100 mg.
Ascorbic Acid (Vitamin C)	100 mg.

Bottles of 50, 100, 500 and 1000 capsules; 4 oz., 16 oz. and gallon syrup.

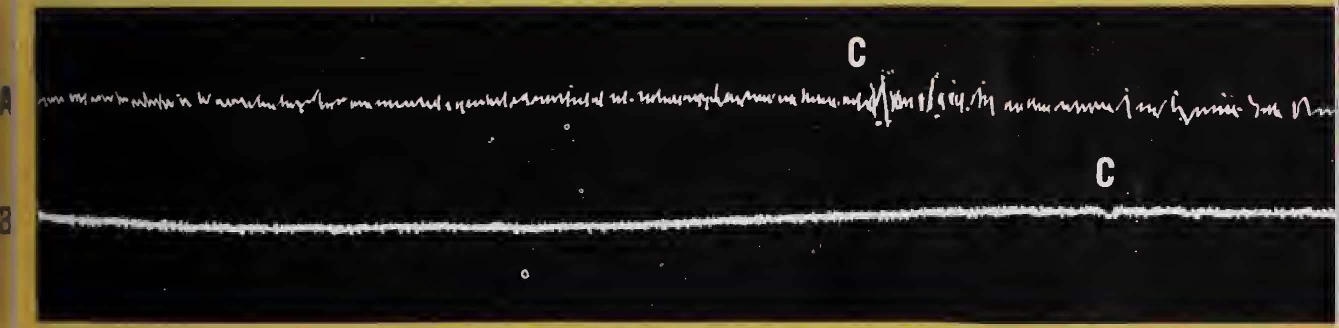
Equanil*

MEPROBAMATE

(2-methyl-2-*n*-propyl-1,3-propanediol dicarbamate)

Licensed under U.S. Patent No. 2,724,720

Electromyography shows decisive response



Electromyographic study of neuromuscular hyperactivity in 42-year-old male with anxiety-tension syndrome. A, Before EQUANIL; action potential of high amplitude and frequency. B, After one week of ambulatory treatment with EQUANIL; showing definite reduction in tension, greater ability to relax, and marked improvement in muscular coordination. C, Point where patient makes effort to relax.[1]

The remarkable effectiveness of EQUANIL may be demonstrated in two ways. One is by its ability to relieve muscle spasm and neuromuscular tension.[1] The second is by its ability to relieve mental tension and anxiety.

Usual dosage: 1 tablet t.i.d. The dose may be adjusted either up or down, according to the clinical response of the patient.

Supplied: Tablets, 400 mg., bottles of 50.

New Booklet Available to Aid Management of Overweight Patients

The 1955 edition of the well-known Knox "Eat-and-Reduce" booklet eliminates calorie counting for your obese patients. This year's edition is based on the use of Food Exchange Lists[1] which have proved so accurate in the dietary management of diabetics. These lists have been adapted to the dietary needs of patients who must lose weight.

The first 18 pages of the new booklet present in simple terms key information on the use of Food Exchanges (referred to in the book as Choices). In the center, double gatefold pages outline color-coded diets of 1200, 1600, and 1800 calories based on the Food Exchanges. Physicians will find these diets easy to revise to meet the special needs of individual patients.

To help patients persevere in their reducing plans, the last 14 pages of the new Knox booklet are devoted to more than six dozen *tested*, low-calorie recipes. Please use the coupon below to obtain copies of the new "Eat-and-Reduce" booklet for your practice.

ADDRESS: REGISTRAR, 707 South Wood Street, Chicago 12, Illinois your patient should not be endangered by fluid accumulation during "rest periods"

YOUR PATIENT NEEDS AN ORGANOMERCURIAL

When a diuretic must evoke acidosis to be effective, continued administration without dosage limitation results in refractoriness. Other diuretics may require interrupted dosage to avoid gastrointestinal irritation.

But the sustained diuresis achieved by the organomercurials never necessitates routine "rest periods" because of their mode of action.

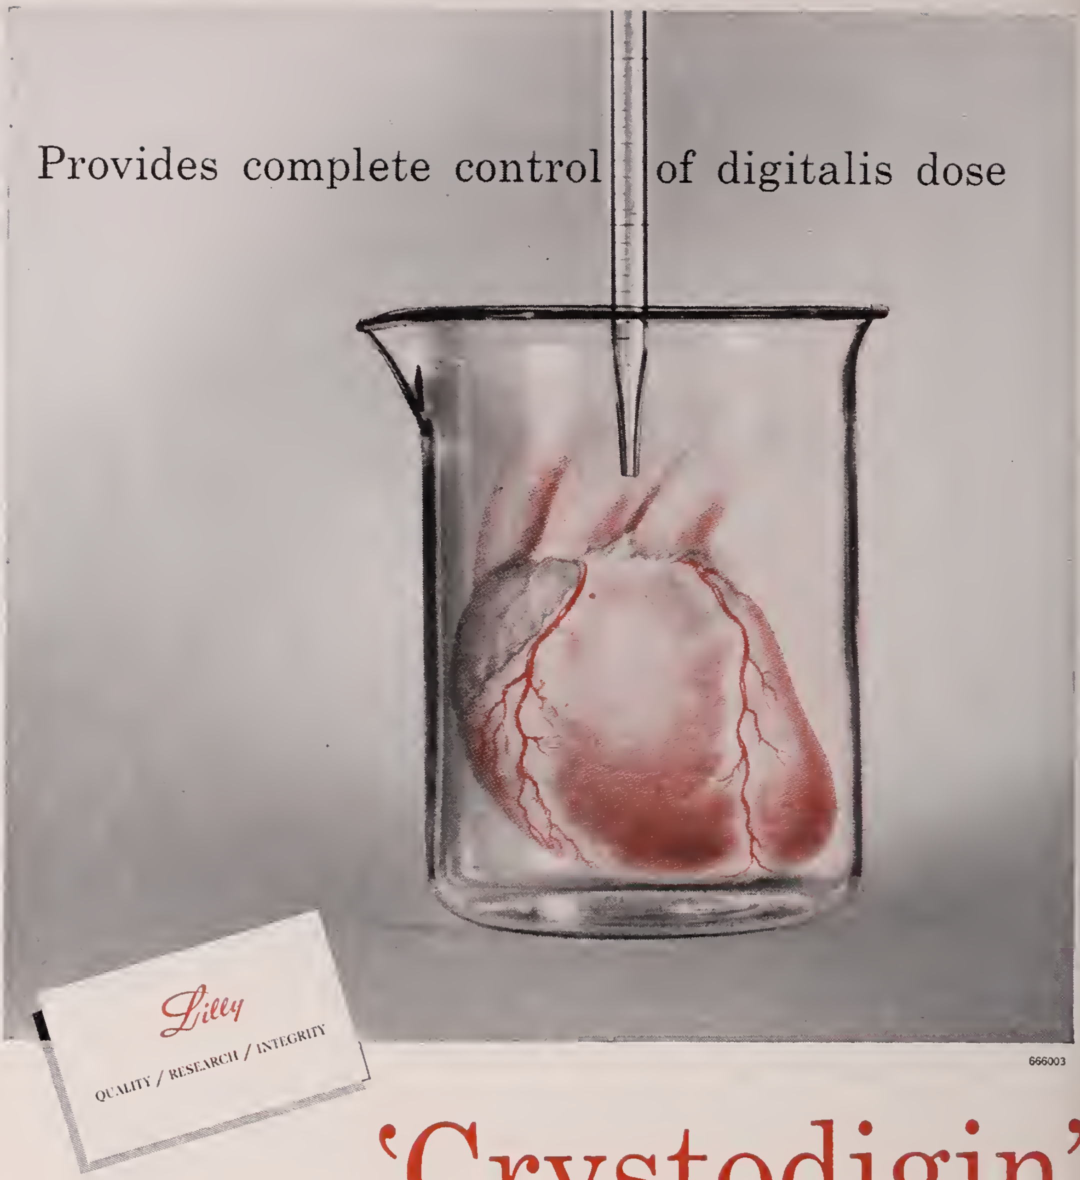
TABLET **NEOHYDRIN**®

BRAND OF CHLORMERODRIN (18.3 MG. OF 3-CHLOROMERCURI-2-METHOXY-PROPYLUREA EQUIVALENT TO 10 MG. OF NON-IONIC MERCURY IN EACH TABLET)

a standard for initial control of severe failure **MERCUHYDRIN® SODIUM**
BRAND OF MERALLURIDE INJECTION

01256

LAKESIDE



Provides complete control of digitalis dose

'Crystodigin'

(CRYSTALLINE DIGITOXIN, LILLY)

. . . . permits accurate dosage titration to produce the maximum therapeutic effect

Since initial digitalization and maintenance dosage must be carefully individualized, 'Crystodigin' fulfills the important requirements of a preferred digitalis. 'Crystodigin' is a crystalline-pure, uniformly potent single glycoside that is completely absorbed in the gastro-intestinal tract. With 'Crystodigin,' the maximum therapeutic effect can be safely determined by dosage titration in increments as small as 0.025 mg.

Available in scored tablets of 0.05 mg. (orange), 0.1 mg. (pink), 0.15 mg. (yellow), and 0.2 mg. (white); and in 1-cc. and 10-cc. ampoules, 0.2 mg. per cc.

Obstruction of the Alimentary Tract
n the Neonatal Period

GEORGE A. HALLENBECK, M.D.
Rochester, Minnesota

OBSTRUCTION of the alimentary canal in the first four weeks of life is rare enough be forgotten easily but common enough to be rt of the experience of almost any physician hose practice includes treatment of babies. ometimes, as in babies who have atresia of some rt of the gastrointestinal tract, the presence of ostruction requiring surgical treatment is obvious on after birth. On other occasions, the presnce of vomiting and abdominal distention in the osence of complete obstruction can make it ifficult to decide whether or not an operation is ndicated. Newborn infants are well able to tolrate even extensive operative procedures on the astrointestinal tract if such operations are perormed when the children have the proper balance f fluid and electrolytes and before they have beome depleted by starvation. Undue delay in ecessary surgical intervention leads to higher oprative mortality rates. Accurate and prompt preperative diagnosis presupposes a working knowldge of the entities likely to produce obstruction n children in this age group, just as adequate surical treatment demands the ability to recognize he various lesions at the operating table and to pply appropriate treatment.

The purpose of this presentation is to discuss roadly the usual causes of obstruction of the limentary tract in the neonatal period and to ndicate the operative remedies that have been ound most effective for each. A list of entities nost likely to be encountered is presented in Table I nd will serve as a framework for the discussion. The first four conditions listed permit accurate diagnosis and the surgeon ordinarily knows the cause of obstruction before operation. The exact diagnosis in the remaining conditions may be suspected or even fairly certain but it is often impossible to make it preoperatively.

TABLE I. COMMONER CAUSES OF OBSTRUCTION OF THE ALIMENTARY TRACT IN NEWBORNS

Atresia of the esophagus
Hypertrophic pyloric stenosis
Malformations of the anus
Incarcerated hernia (inguinal or diaphragmatic)
Atresia or stenosis of the intestine
Incomplete rotation of the midgut
Meconium ileus
Duplications of the intestinal tract
Obstruction associated with Meckel's diverticulum
Annular pancreas
Aganglionic disease of the colon

Atresia of the Esophagus

Atresia of the esophagus means complete interruption of the lumen of the gullet, an anomaly that rarely occurs alone, usually being encountered in conjunction with a fistula between the esophagus and the trachea. The upper segment of the esophagus ends blindly and the lower end communicates with the trachea in more than 90 per cent of cases. In the few remaining cases, either the upper segment or both segments join the trachea. In the common variety, air from the trachea has ready access to the intestines, which promptly acquire the normal gas pattern visible on roentgenologic examination. What is more important, gastric contents and spilled-over saliva are prone to enter the respiratory tract, where they cause pneumonitis. It is of great importance that the diagnosis be made early so operation can be performed before widespread pneumonitis increases the risk to the patient.

The two signs that should make one think of possible atresia of the esophagus are excessive salivation and apparent inability to swallow. Salivation is almost continuous. Although babies so

From the Section of Surgery, Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

affected usually try to eat, swallowing is followed by coughing and cyanosis. Faced with this situation, the physician should try to pass a small rubber catheter into the esophagus. If its progress is blocked in the upper part of the thorax, esophageal atresia may be present. A few drops of iodized oil injected into the catheter before a roentgenogram is made will delineate the blind end of esophagus and usually will demonstrate the absence of a fistula between this blind end and the trachea. If the roentgenogram also shows air in the intestines, as it usually does, the presence of a fistula between the trachea and the lower end of the esophagus is established (Fig. 1). Use of excessive amounts of iodized oil is to be avoided.

If untreated, children who have this disorder die in a week or so of pneumonia and starvation. The earlier the diagnosis is made, the better is the child's condition likely to be and the better are his chances to survive operation.

Once the diagnosis is made, the baby should be placed in a semisitting position with suction applied continuously to the esophagus to minimize the chance for secretions to enter the lungs; antibiotics should be administered, oxygen should be provided by means of a tent or incubator and an attendant should be constantly present to clear the mouth of secretions, should they accumulate. If the diagnosis has been made late, time may be required for the pneumonitis to improve and for hydration by intravenous injection of fluids.

In the earliest era of surgical treatment, successes were few and far between and followed an interminable and expensive series of operations in which the gullet was exteriorized in the neck, the tracheo-esophageal fistula closed, gastrostomy performed and a subcutaneous channel constructed between the esophagus and stomach. This cumbersome method has been abandoned in all but a few unusual cases in favor of one-stage closure of the fistula and end-to-end anastomosis of the esophagus performed as soon as possible after birth. At the present time, a survival rate of 50 per cent appears acceptable, although better results have been reported.[1] Haight,[2] who was instrumental in introducing the one-stage operation for tracheo-esophageal fistula, recently reported recovery in ninety-four (58.7 per cent) of 160 patients operated on between 1939 and 1955. Fifty-one (67.1 per cent) of seventy-six patients operated on during the last five years recovered. Seven died later, leaving forty-four (57.8 per cent) of the original group living. Survivors do exceedingly well. Perhaps a third will need occasional dilatation of the esophagus during the first year or so of life.

Hypertrophic Pyloric Stenosis

Hypertrophic pyloric stenosis, the most frequently occurring lesion on this list, is the familiar obstructing hypertrophy of the muscle in the pyloric region; it is commoner in boys than in girls. Vomiting seldom occurs before the tenth day of life and the vomitus virtually never contains bile; these facts are of great aid in differentiating pyloric stenosis from atresia and pronounced stenosis of the intestine, in which vomiting is present soon after birth, and from other causes of obstruction distal to the ampulla of Vater, in which vomitus containing bile is regularly present. Presence of visible peristaltic waves passing from left to right across the upper part of the abdomen after feeding is typical. With persistence, the pyloric tumors usually can be palpated. The Ramstedt operation of pyloromyotomy, in which the serosa and muscularis on the anterior aspect of the pyloric tumor are incised longitudinally to allow the underlying mucosa to bulge into the defect, carries a postoperative mortality rate of less than 1 per cent and gives results that are among the best in the realm of surgical treatment.

Malformations of the Anus

The embryo passes through a period in which the urogenital tract and the intestine share a common cloaca separated from the exterior by a cloacal membrane. The genitourinary system and the rectum normally become separated completely and the rectum gains its normal opening in the perineum. Arrest of this process can produce a variety of malformations estimated to occur once in 5,000 births. The classification of imperforate anus of Ladd and Gross[3] is useful in organizing these disorders. This distinguishes four main types as follows: Type 1, stenosis at the anus (6 per cent); Type 2, membrane obstructing anus (3 per cent); Type 3, imperforate anus with rectum ending above it (87 per cent) and Type 4, normal anus with rectal pouch ending blindly above it (4 per cent).

In about 70 per cent of cases, the anomalies have associated fistulas connecting the rectum with the urinary tract, vagina or perineum. Such fistulas occur in about 15 per cent of Type 1 and

Type 2 abnormalities and in about 80 per cent of Type 3 malformations. In males, the fistulas are ectovesical, rectourethral or rectoperineal. In emales, the fistulas are between the rectum and he vagina, or the rectum and the perineum.

The Type 1 anomaly, anal stenosis, is usually reated best by dilatation, although anoplasty occaionally may be necessary.

The Type 2 anomaly is treated by incising or xcising the obstructing anal membrane, keeping he anus patent by dilatation afterwards.

The Type 4 anomaly sometimes can be treated by incision per rectum followed by dilatation if he upper segment is near enough to the lower one. In other cases, an abdominoperineal operaion with anastomosis performed perineally after Swenson's technique is the preferable definitive operation; temporary colostomy may be the best way to tide the infant over the first nine months or year of life.

Some Type 3 anomalies can be treated by means of a perineal approach, whereas others require a combined abdominoperineal operation. In general, if the rectal pouch is within 1.5 cm. of the perineal skin or if a rectoperineal or low rectovaginal fistula is present, repair from the perineal approach is possible and should be done as a primary procedure. In the other cases, one either can perform colostomy and defer the definitive operation or can carry out the abdominoperineal pull-through procedure at birth. The one-stage procedure is probably preferable when good anesthesia for newborn infants is available, when the surgeon's experience in both the technical details of such operations and the rather exacting postoperative care justifies it, and when the baby is lusty, weighs more than 6 pounds and has no other serious anomalies to increase the risk. Any fistulas with the vagina or the urinary tract are disconnected at this time. Colostomy is still a good operation when circumstances justify it. Use of the transverse colon leaves the sigmoid free for later use but probably is followed more frequently by prolapse than is sigmoid colostomy. The latter is satisfactory if it is done as near the descending colon as possible.

Incarcerated Hernia

Incarcerated inguinal hernia needs no explanation. Its presence should be obvious if it is sought. Treatment, if attempts at reduction fail, consists of surgical reduction and repair of the hernia. If the hernia can be reduced, often with the aid of sedation, it is advantageous to allow a day or so to pass before repair is attempted, since the edema of the sac that regularly accompanies incarceration makes the tissues friable and somewhat more difficult to handle than is the case when repair is elective.

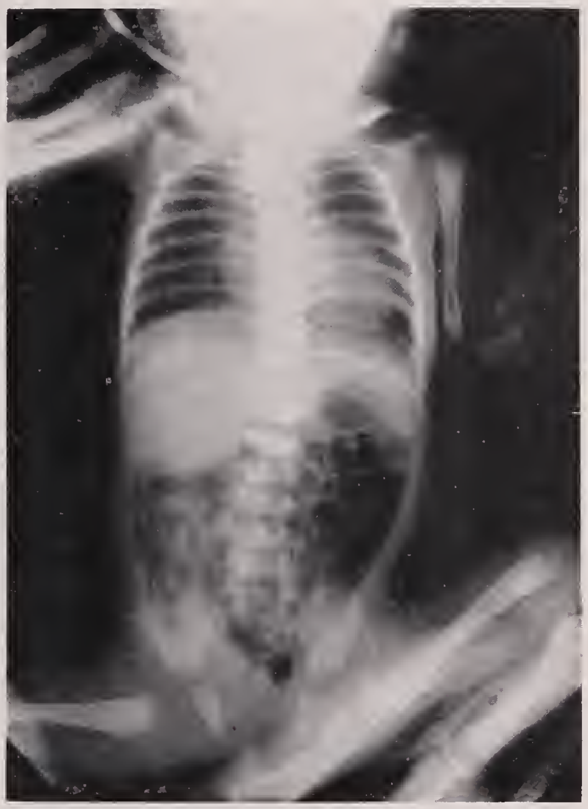

Fig. 1. Plain roentgenogram from a newborn infant with atresia of the esophagus and a tracheo-esophageal fistula. The catheter and iodized oil delineate the blind end of the upper portion of the esophagus. The presence of air in the intestine proves that the lower end of the esophagus communicates with the respiratory tree.

Congenital diaphragmatic hernias, usually through the posterolateral portion of the diaphragm, may allow varying portions of the liver, spleen, stomach, small intestine and colon to migrate into the right or left thoracic cavity. Vomiting caused by obstruction may be present, although cyanosis and dyspnea due to compression of a lung are often more prominent findings. The diagnosis can be made readily by plain roentgenograms, which show evidence of abdominal viscera in the thorax. Surgical repair of the hernial opening should be carried out through an abdominal approach as soon as possible.

Less Obvious Causes of Obstruction

Once patency of the esophagus and anal canal is demonstrated and the presence of pyloric stenosis and hernias is excluded, one can assume that the newborn child who vomits either has a feeding problem that may respond to changes in the formula or has one of the other types of organc obstruction listed in the table. The task of differentiating infants for whom laparotomy is indicated from those for whom medical measures should be employed can be difficult at times, but the severity and unremitting nature of the obstructive symptoms in babies with organic obstruction make the decision to operate clear in most cases. Once the signs and symptoms have suggested intestinal obstruction, plain roentgenograms of the abdomen taken with the child in the upright and supine positions become the mainstay of diagnosis. Although it occasionally may be necessary to introduce barium sulfate into the stomach or colon, use of a contrast medium is unnecessary in most instances. Characteristics of these roentgenograms will be mentioned as the various lesions are discussed.

Atresia or Stenosis of the Intestine.—Either atresia, meaning complete loss of continuity, or stenosis may occur in any part of the small intestine or colon; multiple sites occasionally are involved. Atresia of the intestine always produces symptoms of obstruction at once; stenosis usually causes symptoms in the first few weeks of life but may be of such modest proportions that trouble does not occur for a year or more. Plain roentgenograms of the abdomen usually will show gas scattered widely throughout the gastrointestinal tract when stenosis is present at some point. If the stenosis is sufficient to produce symptoms of obstruction, dilatation of part of the alimentary canal above the lesion usually is present. In these cases, study by means of barium can be revealing. When atresia is present, gas can go no farther than the atretic segment and, particularly when the atresia is in or above the midjejunum, the roentgenogram can be diagnostic (Figs. 2 and 3).

Treatment is surgical in either of the situations just described. The intestine beyond the site of stenosis is typically large enough that side-to-side anastomosis between it and the dilated intestine above can be done without difficulty. Stenosis of the duodenum below the papilla of Vater is b
handled by duodenojejunostomy, whereas th
above the papilla requires gastroenterostom
When atresia is present, the intestine distal to t
atresia is empty and extremely small, while th
proximal to it is hugely distended. Even after t
dilated segment has been decompressed and t
other segment distended with saline, considerab
disparity remains between the sizes of the tw
Because of this, side-to-side anastomosis natura
was favored by most surgeons. Gross[3] noted th
although good results frequently were obtain
when jejunal atresia was treated by this metho
fatality rates for anastomosis in the ileum we
extremely high. He obtained better results
exteriorizing the two blind ends as a doubl
barreled ileostomy, clamping the spur between t
ends later by the old Mikulicz technique and fina
ly closing the ileal stoma. Others[4-7] favor prima
anastomosis with decompression of the proxim
loop of intestine by means of an enterostomy tu
and end-to-end union of the parts despite the di
ference in their sizes.

Incomplete Rotation of the Midgut.—Durin
intra-uterine life, the midgut undergoes rotatio
in a counterclockwise direction, with the superi
mesenteric vessels as its axis. As a result of the
movements, the cecum comes to lie in the rig
lower quadrant of the abdomen and the transvers
colon comes to lie in front of the superior mesenteric vessels and duodenum. Fusion of the root
the mesentery of the small intestine and that
the right portion of the colon to the posteri
body wall follows this process and establishes th
normal anatomic state. This process can be interrupted at any stage. The result sometimes
relatively unimportant, as when the cecum is un
usually mobile, whereas at other times it is productive of intestinal obstruction. The latter ma
or may not be severe enough to cause recognizabl
trouble during the neonatal period.

Obstruction can be caused by either or both
two mechanisms, namely volvulus of the entir
small intestine, made possible by the lack of attachment of its mesentery to the posterior bod
wall, and obstruction of the duodenum caused b
extrinsic pressure applied to it by a band of fibrou
tissue attaching the misplaced cecum to the bod
wall to the right of the duodenum. Described b
Ladd,[8] in 1933, this attachment is often referre
to as Ladd's band. Obstruction caused by incom

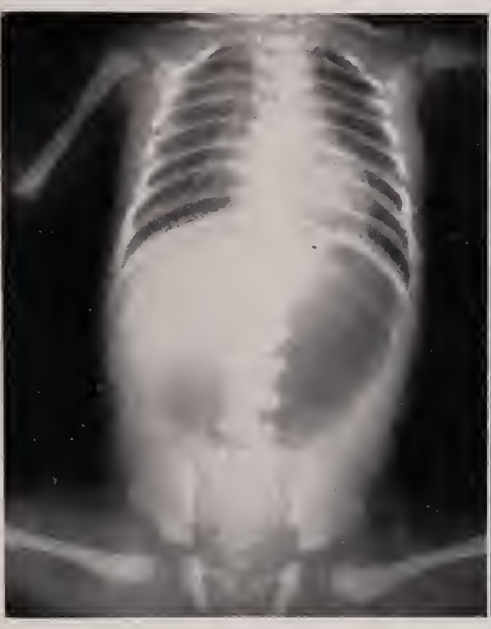

Fig. 2. Plain roentgenogram from a newborn infant with atresia of the duodenum. The gas shadows are limited to the stomach and the first portion of the duodenum.

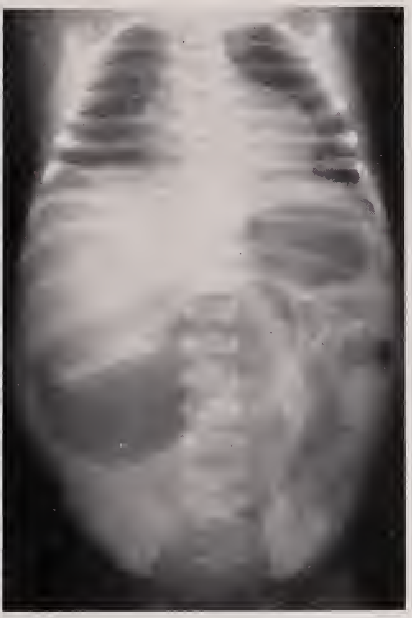

Fig. 3. Plain roentgenogram from a patient with atresia of the jejunum. Gas is evident in the stomach, duodenum and part of the dilated jejunum, but the usual pattern of gas scattered throughout the small intestine is not present.

lete rotation of the gut may appear complete n some instances of volvulus or it may present s incomplete obstruction of the duodenum when add's band is the prominent factor. Roentgeno-ogic examination of the colon and the duodenum with the aid of barium sulfate can be helpul if the symptoms are mild enough that indicaions for surgical intervention are not clear-cut. When it is obvious that an operation is needed, my associates and I choose to spare the infant the tress of these tests.

When the abdomen is opened, one sometimes finds the cecum in the epigastrium or even to the left of the midline and one sometimes finds all the colon hidden by small intestine, which may be of dusky color as the result of volvulus. When this small intestine is delivered from the wound, it is seen to be twisted, usually in a clockwise direction, around its mesentery. The volvulus should be reduced. The picture can be confusing; one must not conclude erroneously that some kind of internal hernia is present and begin fruitless dissection with this in mind. Once the volvulus has been reduced, the cecum and ascending colon in all cases must be freed of attachments on their right and displaced to the left side of the abdominal cavity, thus reproducing an earlier stage of embryologic development. This completely liberates the duodenum. Failure to do this may mean continuation of obstruction. For some reason, recurrence of volvulus is rare.

Meconium Ileus.—This is a form of intestinal obstruction in the newborn in which the terminal portion of the ileum is plugged and obstructed by unbelievably sticky mucilaginous meconium. It is part of a more widespread disorder, including fibrocystic disease of the pancreas and production of extremely thick sticky mucus in the intestinal and respiratory tracts. The great diminution in secretion of digestive enzymes by the pancreas is credited with allowing the meconium to become viscid enough to obstruct the gut. If the child can be tided over this crisis, he will have nutritional difficulties because of poor absorption of food and will have chronic infection of the respiratory tract. In many cases, the former condition can be controlled fairly well by oral administration of pancreatic extracts and the latter by use of antibiotics. Plain roentgenograms of the abdomen in this condition may show a disparity between the size of loops of distended small intestine, associated with the presence of tiny flecks of calcium. Masses sometimes can be palpated in the abdomen.

Perforation of the intestine occasionally has occurred before operation can be performed; perhaps it can happen prenatally. If this is the case, the peritoneal cavity may be obliterated, with dense adhesions causing agglutination of loops of intestine. The outlook in such cases is hopeless. In other cases, the technical problem is one of relieving the obturating obstruction in the terminal part of the ileum. Efforts to remove sticky meconium from the intestine usually fail, although some successes have been reported.[9] Gross[3] has reported better results after removal of the dilated portion of ileum that contains the semisolid meconium by means of the aseptic Mikulicz exteriorization technique already mentioned. The proximal opening serves as the ileal stoma, whereas the distal opening is an orifice into which solutions of enzymes can be perfused to clear the distal part of the ileum and the colon of meconium. The spur is clamped and the opening is closed later.

Duplications of the Alimentary Tract.—These duplications, sometimes called "enterogenous cysts," may occur any place in the alimentary canal. They vary in shape from small or large spherical structures closely attached to the gut to long tubular organs paralleling the intestine. Some are closed, whereas some communicate with the intestine and are, therefore, like diverticula. Obstruction is only one of several ways in which these structures can produce symptoms. When obstruction occurs, it is usually because a tensely filled cyst attached to the gut applies pressure to it. Only twenty of sixty-eight patients reported on by Gross[3] required treatment during the first four weeks of life. Duplications of the intestine are best excised. Usually they are in such close contact with the intestinal tract, sharing its blood supply, that adjacent intestine also must be removed.

Meckel's Diverticulum.—An occasional example of Meckel's diverticulum has a fibrous cord attaching its tip to the navel or to the root of the mesentery. Loops of small intestine can become incarcerated behind or around such a band to become obstructed or even gangrenous. The situation is dealt with as it would be in the adult.

Annular Pancreas.—A rare disturbance in t embryologic development of the pancreas cau a ring of pancreatic tissue to surround the seco portion of the duodenum. This anomaly may asymptomatic, may cause mild obstruction not only in adult life or may produce a high deg of obstruction of the duodenum, requiring tre ment in the neonatal period. Duodenojejunostor gives good results, being preferable to gastroent ostomy and probably to direct attack on the co stricting ring.

Aganglionic Disease of the Colon.—Congen absence of ganglionic cells in Auerbach's plexus the distal part of the colon, the anomaly th causes Hirschsprung's disease, or aganglionic meg colon, and that is always associated with obsti tion in the neonatal period, may produce virtua complete obstruction with diffuse distention of entire small intestine and proximal portion of colon. When gross lesions cannot be found laparotomy for intestinal obstruction in a newbo infant, one must think of this disease. Megacol develops later as a result of obstruction offered the faulty terminal segment of colon and is present at birth. Extramucosal biopsy of the rec sigmoid may provide the diagnosis, since ganglionic cells will be absent in Auerbac plexus between the circular and longitudinal lay of muscle. Often the diagnosis will be presum tive, however, and one is justified in making transverse loop colostomy in such cases, plann to carry out Swenson's operation later.

Summary

A review has been made of pertinent poi concerning the various types of obstruction of alimentary canal likely to be encountered dur the neonatal period. Such information is essen to the physician and surgeon who must diagn these conditions and treat the children so affect The safety factors in the surgical treatment such infants are smaller than they are in adu Experienced anesthesiologists and an understa ing of the management of fluid and electrol balance in infants are essential to success. though disappointments are common and althou multiple and sometimes hidden anomalies ot than the one being treated can thwart succ good results often are achieved and are extrem gratifying.

Treatment of Varicose Veins

A Twenty-five Year Reflection

H. O. MC PHEETERS, M.D.
Minneapolis, Minnesota

TIME, and time alone, will give the best and most conclusive answer to all questions relative t the value of any method of treatment in the fid of medicine. It is the checking up on our rk and end results from year to year that finally mits us to say, with conviction: "This is the best thod of treatment today." After twenty-five rs of treating varicose veins, we can assess our d results and say "This is the best method of ating varicose veins as of today."

Even before the days of Hippocrates, varicose ns were recognized as a cause of pain and dis-ility. Probably no pathological condition has eived more study and effort at correction than s varicose veins. The early efforts were incor-t and held a high mortality rate, and the mod-n era of treatment really dates from the inven-n of the hypodermic syringe by Dr. Pravaz in 54.

The next great step was in 1892 when Trendel-burg[1] recognized and proved the reverse flow of od in the varicose veins by the test that now ars his name. During intervening years efforts r the elimination of the varicose veins have in-ded in the main injection and operative meth-s. First one would be claimed the better and en the other. Each era and cycle would be an provement over the other. The solutions used r the injection treatment were corrosive and structive. In 1908 some countries forbade their e. Study and research have corrected many of e errors, and today we inject varicose veins with punity, and for the selected case it is the ideal ethod.[2,3]

Following the Trendelenburg teachings several stinguished surgeons such as Charles Mayo, Bab-ck, Homans, Mataz and others spent much ef-rt developing operative methods for the removal the varices. Their efforts were attended by high ortality rates due to thromboembolism.

It was Sicard in 1914 and Linser in 1921 that first developed the idea of ambulation following the treatment. Their injection treatments were carried out as outpatient services. It was their improved results in comparison with those following surgery that impelled me to carry on.

TABLE I.

1932 through 1949	5791 Ligations with retrograde injection and follow-up injections.
1950 through October, 1955	5147 Ligations with stripping and follow-up injections.

In 1928 my short term results were so good that I advocated the injection treatment of all cases of varicose veins.[4] As time went by I realized my error after seeing many moderate cases and almost all of the severe cases recurring. Still these efforts and successes were an improvement over anything done before. My sixty-fifth case died of a pulmonary embolus but the pathologist who did the autopsy decided the embolus most probably came from a pelvic infection which she had at the time.

During this same time surgeons were correcting their errors and doing better work with the consequent reduction of pulmonary emboli.

The next forward step was a combination of the two methods of treatment, doing a ligation of the veins in cases of proven reverse flow, and the use of the injections to obliterate the veins below.[5,6] It was only after years of work that surgeons realized that the best end results were achieved with the ligation high *"above"* all tributaries and flush with the wall of the femoral vein at the saphenofemoral junction.

John Homans[7] was the first surgeon to emphasize this particular bit of technique. To him we must give credit for laying the foundation for our present-day success. Numerous papers were written on the subject of the *new* and *modern* treatment of varicose veins by doing the high saphenofemoral ligation followed either immediately or later with injection of the distal segments.[5,8] Sev-

Presented before the Hollywood Academy of Medicine, ollywood, California, September 9, 1954.

eral movies[9] were made to show the detailed technique, and we thought we had reached the ultimate in the treatment of varicose veins.

During the period of 1945 to 1947 I tried to assess my results, not in periods of months, but of years. Even though we had tried to do the best surgery we could with careful follow-up injections in all cases, we often found complete failure with the ligation and retrograde injection treatment of varicose veins. They often recanalized and became as large as when first seen.

Further study of these cases would often show a good sapheno-femoral ligation with the proximal stump closed but with the percussion pulse (P.P.T.) felt through the lower thigh and disappearing in the mid or upper thigh. The multiple tourniquet test would show that the reverse flow came from the mid or upper thigh but not from the groin. In many cases we found the reverse flow was from a perforator vein in the lower leg. We then started picking up the recanalized vein internal to the knee and passing the stripper upward. To our surprise we found it would often pass up to the fibrosed segments just below the main scar at the groin. The stripping of this segment upward would often reveal a perforator or communicating vein in the mid or upper thigh. In passing the stripper downward we found many perforator veins in the lower leg as a cause of recanalization.[10] This stimulated greater study to locate the perforator or communicating veins before any surgery was done, and we found that with more careful examination the incompetent perforator veins could usually be located and marked before the primary operation was done.[11] This combination of a careful preoperative examination and study of each individual case followed by "adequate" surgery for the case at hand and then the use of injection treatment for the scattered and remaining small, tortuous, varicose segments, has produced a good and lasting result in practically all cases.

"Adequate" surgery, mentioned above, refers to a ligation flush with the femoral vein above all tributaries, followed by stripping and dissection of all the main varicosed segments below, with injection of all small scattered tortuous segments remaining.[12,13] A simple high ligation by itself, as advocated by some surgeons, has proved to be a failure in so many cases that it can be mentioned only to be condemned.[14]

It must be stated at the outset that we believe that the great majority of varicose veins are be explained by a weakness of the vein wall, permi ting it to dilate and thus render the valves i competent, permitting the reverse flow blood.[15,16] We do see some cases of congenit varicose veins, and instances of congenital arteri venous fistulas occur. In other cases there h been a destruction of the valves in the veins l phlebitis. Any of these factors render the vei more vulnerable to the increase of the intr abdominal pressure associated with work, hea lifting and pregnancy. Moreover, if the wea ness persists, we must expect additional varico veins to form as the years go by. Experien has proven this to be true.[17]

Varicose veins occurring during pregnancy m be an aggravation of pre-existing varicosities, b many cases with rapid formation and develo ment must be explained on some other basis.

There is much evidence in support of t theory that the smooth muscle and connecti tissue of the body loses its tone and relaxes wi pregnancy. The vulvar muscles and pelvic lig ments also relax. Pregnant women often devel a hydro-ureter many times the size of a norm ureter and yet it will rapidly return to norm following delivery. The urological examinati does not reveal evidence of pressure and obstru tion to account for this. Often varicose vei develop rapidly over the thighs and lower le during the second and third month of a pre nancy. At that period of gestation the uteri fundus is not large enough to cause either obstru tion of the ureter or of the venous flow fro the lower extremity.

This can perhaps be best explained on a ho monal basis.[18] The intramuscular administrati of ovarian hormones (Estro Luteum Solutio Lincoln Laboratories) has given marked relief the pressure, pain and fullness in many cases.[19]

The best results are obtained when the hormo therapy is started before the third month a continues through the sixth month. The usu methods of relief, elastic bandages on the low legs with elevation of the lower extremities f twenty minutes three times a day, should be co tinued.

Probably the foremost point in the treatme of varicose veins is the individualization of thera to the particular needs of the patient. Ea patient must be studied separately with a detail history and thorough examination. Venous p ology must be differentiated from arterial pa- ology. Individuals with familial, hereditary vari- se veins must be given a different prognosis than ose with the postphlebitic syndrome. In- viduals with stasis edema must not be classified the same category as those with lymphedema lipedema. Swelling may be due to incompe- nt veins, hypothyroidism or cardiorenal disease. he pain may be due to varicose veins, arthritis, pped disc, or local inflammation. Differential agnosis is just as important in peripheral vas- lar disease as it is elsewhere.

The history of onset is important. Did the ouble come on gradually or rapidly; at what ge; was there an injury, illness or operation about he same time; was a pregnancy involved?

The majority of patients seen by the vascular rgeon are at least middle aged, although the ondition may have been present for several years. his age group can have arterial or venous isease, or both. The typical patient with ar- eriosclerosis gives a history of cold extremities nd claudication; the pain comes on after walking fairly definite distance and disappears within a ew minutes after the patient stops walking. Night ain and ulceration are late manifestations. Ex- mination of the arteriosclerotic lower leg usually eveals a pale, dry skin, often resembling parch- nent. A cold, wet, clammy skin usually indicates asospasm.[21] Rubor, especially of the toes and specially near an infected ingrown toe nail, is ommon. Trophic changes include loss of hair nd ridged nails. The skin temperature is often to 10 degrees below normal. The dorsalis pedis nd posterior tibial pulsations are diminished or bsent and the oscillometric readings are low. There is usually no swelling unless infection is resent or the patient sleeps with the lower leg anging over the edge of the bed for comfort. rterial ulcerations are usually located on the oes, heel or lateral surface of foot and ankle.

Seventy-five per cent of the patients with venous pathology have a familial history of varicose veins and often these patients will describe exacerbations with pregnancy or following a period of inactivity due to injury or illness. The typical findings of enlarged superficial veins, edema and cyanosis easily account for the tired, heavy feeling later in the day. Prolonged standing or sitting causes pain which is relieved by quick calf muscle contractions. Nocturnal leg cramps are a common complaint before surgical treatment. Stasis pigmentation gradually increases as long as the swelling is unchecked. It very slowly fades if good circulation is re-established. Varicose ulcers are usually located on inner lower leg and can be temporarily improved by elastic support, frequent calf muscle contractions and rest periods. Definite treatment requires careful search for, and elimination of, any varicose veins running under or feeding into the ulcer.

Differentiation as to Source of Reverse Flow

Which system is involved—long saphenous or short saphenous, or both?[22] This is determined by percussion pulse transmission (P.P.T.) and the Trendelenburg test. These two tests form the basis for any good examination and give information obtainable in no other way. The P.P.T. helps us chart the course of the veins. The Trendelenburg test helps locate the origin and determines the amount of leakage. Not infrequently the reverse flow originates in the long saphenous but, because of communicating vessels, the short saphenous veins are enlarged, and vice versa.

Often one or more incompetent perforator veins allow reverse flow into and cause dilatation of, the long or short saphenous system. Good therapy requires ligation of the perforator vein and closure of the defect in the fascia. The perforator veins should be diligently searched for and their location carefully marked *before* surgery.[11,12] They can be felt as true openings, in the fascia. Finger tip pressure in these soft spots or holes is painful, as is the stretching of any opening in the deep fascia. Perforator veins are most commonly found on the internal surface, mid and lower thirds of lower leg. They may occasionally be located below the internal malleolus and feed upward into an ulcer, keeping it open. They may sometimes be felt in the base of a healed ulcer or dermatitis area and may be the cause of frequent recurrences. The Trendelenburg test helps to locate these perforators. If the veins below the tourniquet fill in ten seconds, you can be sure that one or more incompetent perforator veins are present.

Treatment of Varicose Veins

Preoperative.—General measures: Eliminate active infection including that due to fungus; encourage habit of frequent calf muscle contraction; reduce obesity; correct systemic conditions such as anemia, hypothyroidism, et cetera.

The very obese patient with varicose veins on the thighs and lower legs will usually have a poor end result. As a rule new varicose veins will form within a few months and they are hard to find and inject well in the obese leg. Such patients are also more liable to develop swelling and edema following radical dissection and stripping.

Surgical.—(1) Large varicose veins with definite reverse flow must be ligated *wherever* the reverse flow begins; the distal segment must be removed by stripping and dissection wherever possible.[8] Perforator veins must be carefully sought, dissected out and ligated.

Ligation at the source, plus retrograde injections of the distal segment, is satisfactory only for a superficial, tortuous vein of moderate size such as the lateral femoral cutaneous type, often found on the antero lateral thigh.[5]

(2) Small varicose veins with no reverse flow can be sclerosed by injection therapy.[4,23]

(3) Skin grafting: If the varicose veins have been present for years with the development of severe chronic cellulitis and recurrent ulcer formation, it may be best to do a radical excision of the area down to the deep fascia and the immediate application of a split skin graft. These patients must wear support for "many months" and often for the remainder of their lives.[24,25]

Postoperative — Careful and complete follow up injection therapy of every case should be done at the office one or two months after surgery and then yearly thereafter.

Post-phlebitic patients with deep vein incompetency may not be entirely relieved of their stasis by elimination of the superficial varicose veins.[27,28] For them the "new way of life" as advocated by Luke[14] is imperative. They must not permit the development of edema. Elastic support, rest periods with feet at least on a level with the heart (the sitting position does not correct the edema), frequent calf muscle contractions, et cetera, all help. If necessary a change of occupation is preferable to the damage caused by constant edema.

Most cases of stasis dermatitis improve with good circulation; stubborn, resistant cases often are benefitted by superficial x-ray therapy. They should be referred to a skin specialist. If the case presents the cold, clammy, wet leg showing evidence of vaso spasm being present, then lumbar sympathectomy will often give mu help.[21,22]

Recurring cellulitis: For this condition v must control the edema, give irradiation therap control the fungus infections about the toes ar feet, and give Gantrisin 2 gm. daily for one wee in each month for four to six months.

Then finally the procedure needed to be do is:

(1) The injection method for the early form tions and small veins with no reverse flow.[4,23]

(2) Ligation wherever the reverse flow begi followed with a complete stripping and dissecti in all extensive cases.

(3) Ligation and then retrograde injection the smaller tortuous varicose veins anterior ar external thigh and lower leg.

(4) Ligation, plus stripping, plus blunt di section, plus retrograde injection of extensive to tuous groups of smaller size 1 and 2 veins.[29,30]

(5) Ligation, plus stripping, plus blunt di section, and even the Linton operation.[15] A times an excision of the old cellulitis and ulc area in the lower leg with skin grafting.

(6) Then a careful and complete follow u injection of every case at the office and the yearly thereafter.

(7) When edema has developed with seconda complications of cellulitis and ulcerations, extern support must be used to control the swelling. Th patient must learn "a new way of life."[26] Th is best done with a *4-inch elastic bandage* wor very firmly applied from just below the knee dow to and about the ankle and foot. The tight the bandage and the faster the patient walks, th better will be the circulation in the lower leg.

In conclusion this plea is made: A careful hi tory should be taken as to the onset and develo ment of the individual patient's disease. Th should be followed with careful and detailed in spection and palpation examinations, combine with the use of the percussion pulse test, (P.P.T and the Trendelenburg test.

The treatment of the patient then should co sist of an *adequate* surgical procedure, *individua ized* for the given case, together with *adequa* observation and care of the patient the rest his life.

The Position of Radiology in Cardiovascular Diagnosis

FRED JENNER HODGES, M.
Ann Arbor, Michig

WITH the passage of time there are fewer and fewer persons who can relate personal acquaintance and memories with individuals whose work has been memoralized by professorships, scholarships or lectureships. To those so fortunate as to cherish personal memories of Russell Daniel Carman, this occasion becomes considerably more than a simple medical discourse for the remarkable personality of a truly great man reaches across nearly thirty years to pervade their thoughts. A driving, dynamic and brilliant physician, utterly devoted to radiology, it was Carman's great capacity for friendship which all who enjoyed it will remember most fondly.

As the veriest of neophytes in radiology, your speaker came under the spell of that freely extended, sincere and stimulating friendship during visits to the section on radiology at the Mayo Clinic and at medical meetings. Although those contacts were brief, 1923 to 1925, the memory of them has been vivid and deeply inspiring over the years. Carman quickly assumed, and correctly, that instruction was called for and upon every contact poured out by impromptu lecture, precept and vigorous example the clear cut essentials of honest and effective gastrointestinal radiology. The lessons he taught have proved to be increasingly valid for they were fundamental. American radiology has yet to produce an abler performer in this particular field, or a finer, more lovable character. It is particularly fitting that the Minnesota State Medical Association has paid lasting tribute to a former member whose professional accomplishments were of world-wide scope and importance. Let those who did not know him in life accept with confidence the validity of perpetuating his memory by dignifying lectures with his name, for he was truly dedicated to the fin traditions of the profession of medicine.

The position of radiology in cardiovascul diagnosis has been so thoroughly altered since 19 that virtually none of its present features wou be familiar to Carman. In his time it was nece sary for radiologists to content themselves wi measuring the size of the heart, observing its po tion, its shape and the pulsations of its borde and noting the appearance of the great vesse Carman, who was so adept at the exploration the alimentary canal with suspended barium su phate, would be intrigued with today's methods studying the lumen of the circulatory system, ar the interest in surgical techniques and surgic pathology which lured him to the operating tab in following interesting radiologic findings wou find ample opportunity for expansion to the ca diovascular field.

The story of the phenomenal change which h occurred in the radiologic approach to cardi vascular problems in this country differs sharp from the early history of radiology in Americ News of Roentgen's discovery of x-rays, announce in December, 1895, spread throughout the civilize world with electric rapidity and in the Unite States patients were being subjected to x-r diagnosis within a few weeks. The *America X-Ray Journal* was established in 1897, and 1900 the Roentgen Society of the United Stat was organized with sixty-four charter members.

In 1924 Brooks, a surgeon, described a meth of injecting sodium iodide into the femoral arte in order to produce radiologic images of t arterial distribution to the lower extremity. Fe radiologists followed this lead. From 1927 throug out the early thirties, Forsmann in Germany, Eg Moniz and dos Santos and associates in Portug brought forth daring techniques for the radiolog study of opacified blood in the heart, the arteri of the brain and the abdominal aorta and i

b nches, but although these methods enjoyed clin- i l recognition in Europe and the Latin American c intries, radiologists of the United States seemed r ictant to employ them.

peripheral capillaries and the chambers of the heart, as well as the entire pulmonary circulation. Radiology has exploited a vast new jurisdiction to add voluminous and intimate knowledge concern-

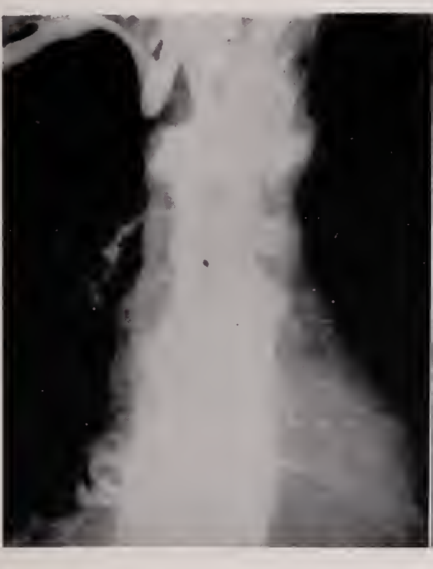

Fig. 1. Complete occlusion of superior vena cava. Injection of opaque material by arm vein fails to result in filling of right atrium.

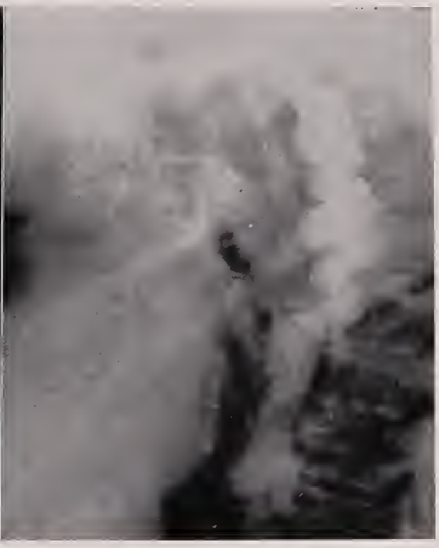

Fig.2. Lateral projection shows extensive filling of tortuous, distended azygos system. Systemic blood from upper extremities must use this route to reach the right heart by way of the inferior vena cava.

It was not until Robb and Steinberg described eir technique and their initial experiences in 39 that angiography began to flourish in Ameri- . An editorial in the *Journal of the American edical Association* of February 15, 1896, offered is admonition regarding x-ray diagnosis: "Its rgical utility in certain ways has probably been fficiently indicated by what has been already one, but enthusiasm as to its future should be mpered by a scientific spirit of moderation that roves all things before building its faith upon em." It would seem that this advice, so blithely nored in 1896, had finally been taken to heart ter a lapse of thirty years, for certainly the new rdiovascular techniques were most carefully rutinized before they finally won widespread ap- roval. Since 1940 the story has been quite dif- rent, for in fifteen years cardiovascular radiology, juvenated by the acquisition of new techniques, as swept forward with accelerating momentum to rilliant clinical accomplishments.

It is now thoroughly feasible and often dramati- ally helpful to visualize the venous system from istal extremities to the right atrium, the arterial ream bed from the origin of the aorta to the ing the morphologic and the physiologic expressions of circulatory disorders. Six basic procedures are used by radiologists in close co-operation with their colleagues in cardiology and surgery: venography, splenoportography, cerebral angiography, retrograde aortography, abdominal aortography and angiocardiography.

Venography

Venography is accomplished by injecting opaque iodine-containing solutions into peripheral veins distal to the point of suspected abnormality. By this means obliterative lesions of many sorts can be demonstrated graphically, as well as the efficacy or incompetency of venous valves in extremity vessels. The procedure which is simple and safe, is often of great utility in identifying the nature of obscure mediastinal lesions (Figs. 1 and 2).

Splenoportography

Splenoportography is employed for the study of the splenic vein and the portal system. Opaque material is introduced by direct percutaneous needle puncture into the splenic pulp, following which several exposures of the upper abdomen are made at intervals of about one second. Under normal conditions the splenic vein fills rapidly, discharging freely into the portal vein and its intrahepatic subdivisions. Within a few seconds the opaque blood fills liver capillaries to the extent that the entire organ becomes visibly opaque. The tributaries emptying into the splenic and portal veins do not fill. When portal hypertension exists, either intra- or extrahepatic in type, findings on x-ray are distinctive and of reliable diagnostic value. The tributary veins now serve as collateral escape routes for blood unable to pass through the normal liver route, and varices of tl stomach and esophagus are dramatically show When abnormal masses occupy the liver they ca be recognized as defects in the hepatogram (Fig 3 and 4). and certain lesions of the pancreas ca be apprehended by the visible alterations pro duced in the course and contour of the splen vein.

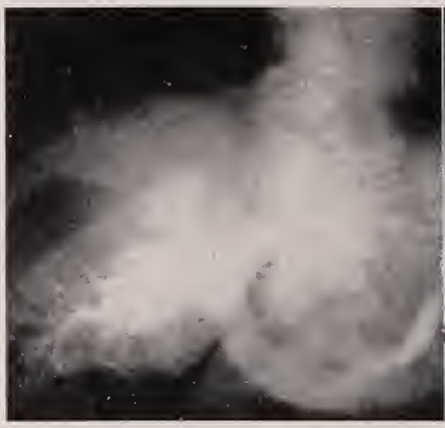

Fig. 3. Early phase of splenoportogram shows absence of portal venous elements in entire upper portion of right lobe of liver.

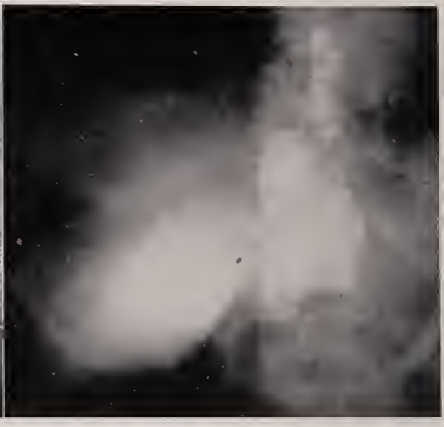

Fig. 4. Later phase, same patient. Lower portion of liver now opacified; upper portion not opacified. At autopsy very extensive replacement of liver by metastatic carcinoma from primary sigmoid lesion resected five years previously.

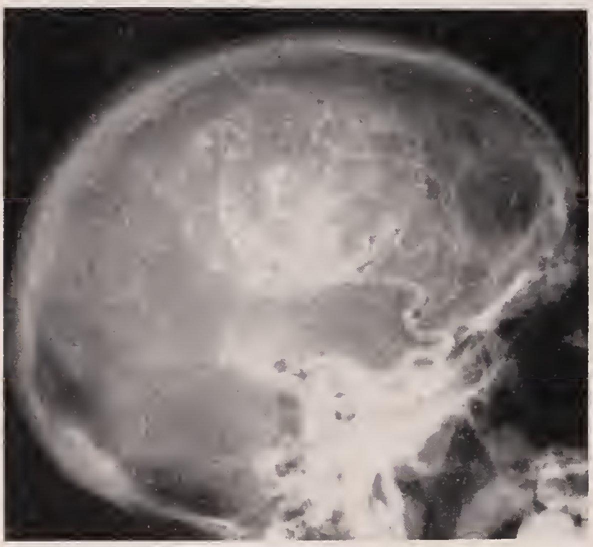

Fig. 5. Large parietal glioblastoma. Displacement of normal vessels. Extreme vascularity of the tumor itself is well shown.

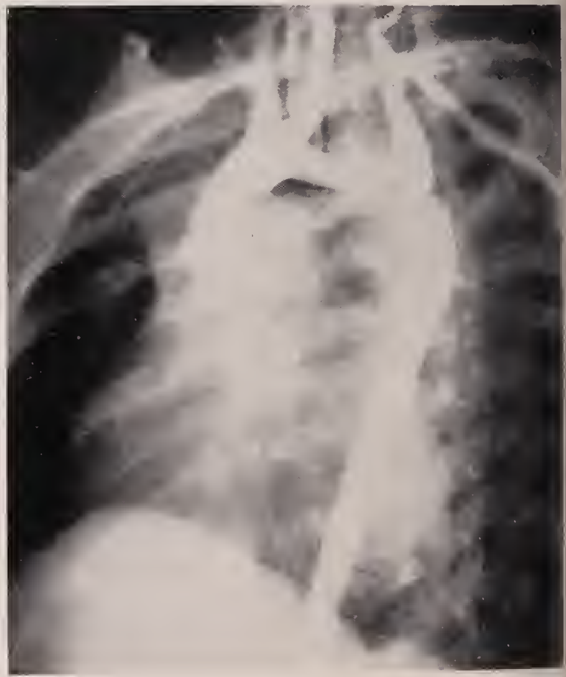

Fig. 6. Retrograde injection of subclavian artery ou lining aortic arch and major branches. Mild degr of coarctation seen at origin of descending aorta a broad, patent ductus arteriosus.

Cerebral Angiography

Cerebral angiography, the radiologic recording intracranial vessels, is accomplished by per- sing the internal carotid or the vertebral artery

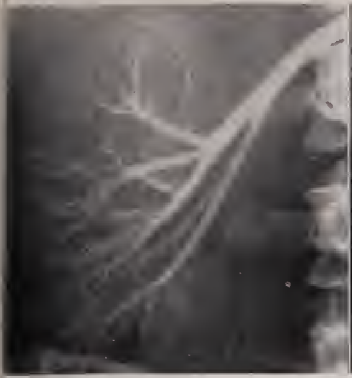

Fig. 7. Selective filling of renal arterial system, right kidney. Needle inadvertently placed in renal artery instead of aorta.

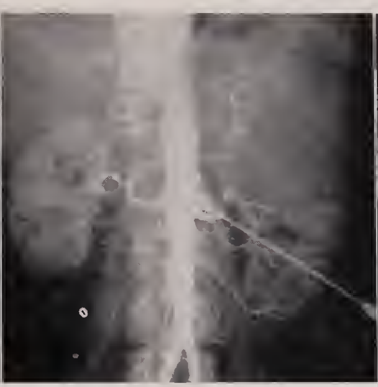

Fig. 8. Abdominal aortogram with normal fill of vessels on right and extensive obliteration of upper pole vessels on left. Large renal carcinoma upper pole left found at operation.

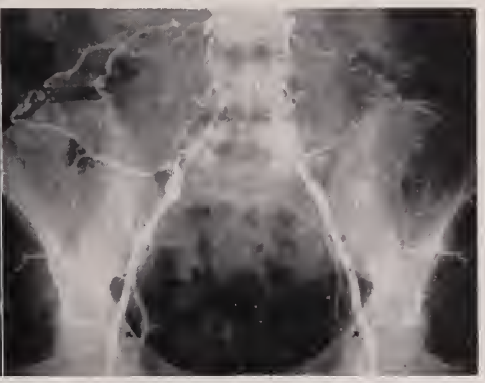

Fig. 9. Abdominal aortogram. Abrupt narrowing of lumen proximal to bifurcation representing prefound atheromatous disease which virtually obliterates lumen of iliac arteries leading to extensive development of collateral arterial channels.

ith opaque material. Ominous as the procedure ounds when first contemplated, this procedure. ntroduced by Egas Moniz, is actually tolerated emarkably well, as well or better than ventriculog- aphy. It is profitable to make x-ray exposures uring the venous as well as the arterial phases of erebral circulation. Using this technique, lesions vhich involve vessels directly as well as those vhich distort and displace vessels can be detected nd localized with remarkable ease and accuracy Fig. 5). In the case of highly vascular tumors ngering opacity within the mass, known as tumor stain," actually renders the tumor visible n its own right. To fully appreciate the status of erebral circulation it is essential to prepare expo- ures in two planes, lateral and frontal.

Retrograde Aortography

To enhance the density of the thoracic aorta nd its branches, the forceful injection of opaque naterial by way of the carotid or subclavian artery gainst aortic pressure is useful and practicable. This procedure is helpful in the demonstration of oarctation of the aorta, aneurysms of aorta or najor branches, anomalous vessels which may be roducing undesirable symptoms (Fig. 6) and for etter understanding of the nature of pulmonary or mediastinal masses lying close to the aortic rch.

Abdominal Aortography

Dos Santos in Portugal was the first to opacify the abdominal aorta by direct percutaneous puncture below the diaphragm and above the renal arteries. This procedure produces a wealth of radiographic evidence concerning intra-abdominal lesions. It is possible not only to recognize intracapsular renal masses but to differentiate in many instances between benign and malignant tumors on the basis of vascular pattern (Figs. 7 and 8). In Sweden clever techniques involving the placement of catheters introduced through the femoral artery directly into individual renal arteries have been successfully employed together with steroscopic filming. It is possible by aortography to visualize the major divisions of the aorta almost at will, and to provide detailed information concerning obliterative lesions of the arteries which supply the lower extremities (Fig. 9). Such information, supplied to the surgeon, often leads to spectacular alleviation of serious inadequacies of circulation for the removal of obstructing atheromatous masses or grafting operations can be planned and executed with great accuracy.

Again in Sweden, catheterization of the iliac artery by way of the femoral, using externally applied pressure to partially occlude the aorta and the femorals, is used to produce lingering opacification of the uterine artery on one or both sides. By this means Fernström is able to demonstrate placental sinuses in the early weeks of gestation. The method is particularly useful in establishing the diagnosis of tubal pregnancy and in localizing

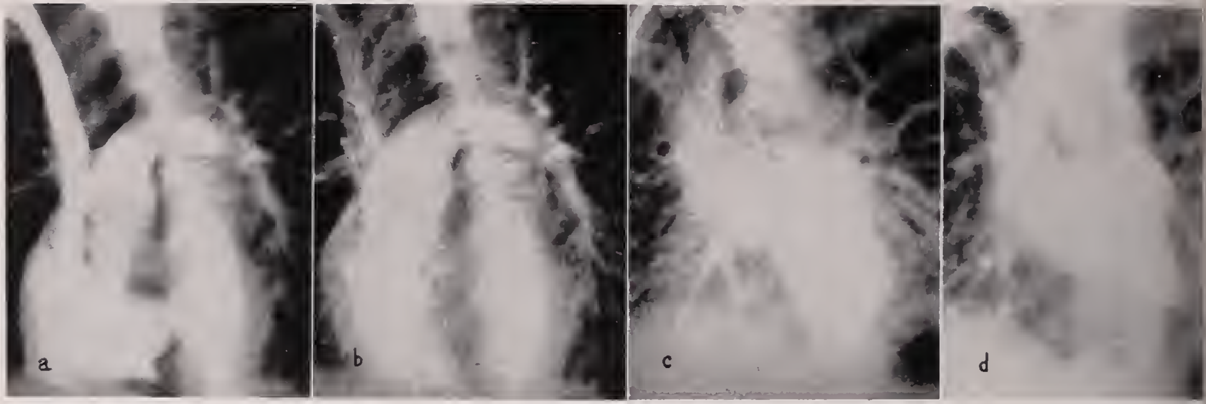

Fig. 10.—Venous angiocardiogram.

(a) Fill of superior vena cava, right heart and pulmonary arteries. (b) One second later right ventricle in diastole shows location of interventricular septum with no filling on left.

(c) Four seconds later opacified blood returning by way of pulmonary veins outlines the left atrium and ventricle. The aorta is beginning to fill. (d) The l ventricle is shown in systole one second later. T arch of the aorta with innominate, left common carot but no left subclavian artery are clearly shown. Loc ized narrowing of the descending aorta (coarctation c be recognized with post-stenotic dilatation.

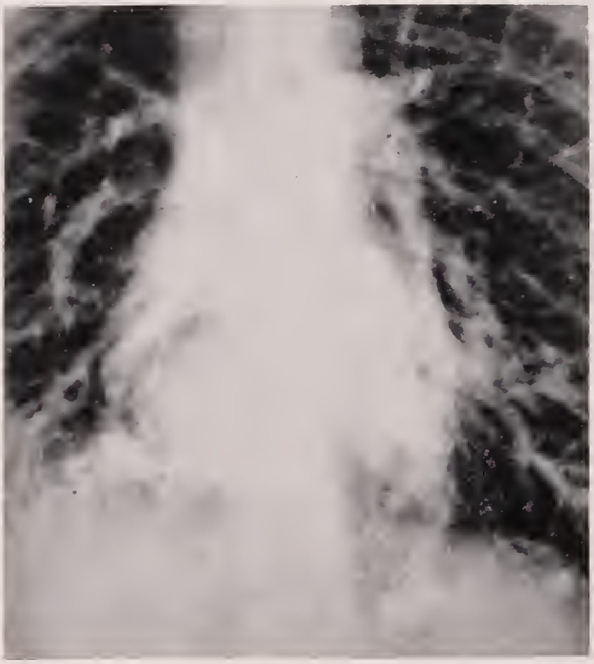

Fig. 11. Venous angiocardiogram showing several pulmonary arteriovenous aneurysms. The largest communication is to be seen below the diaphragm contour on the left. Although the exposure was made only a few seconds after injection the left auricle and ventricle are filling prematurely as the result of these pulmonary shunts.

the position of the placenta in normal intrauterine pregnancy.

Angiocardiography

The radiologic procedure most extensively used in cardiovascular diagnosis is angiocardiography. This can be done by the venous route or by selective injection through catheters. When injection made through the antecubital vein, all chambe and vessels from the vena cava to and includi the aorta are successively opacified. Exposures short time intervals serve to record importa events of the central circulation (Fig. 10). A wi variety of congenital malformations yield distin tive radiologic evidence of their presence ar character. The method is of great value in dete mining which patients with congenital heart d ease may hope to benefit by surgical treatme Not infrequently the surgeon can determine advance what difficulties he may expect to e counter. Tetralogy of Fallot, transposition of gre vessels, septal defects, infundibular and valvul pulmonic stenosis and patent ductus arterios lend themselves well to this method of exact dia nosis.

When properly employed in conjunction wi accurate cardiac catheterization utilizing pressu determinations, oxygen concentrations, simult neous electrocardiography and electrokymograph angiocardiography reaches its peak of diagnost accuracy. Specialized radiographic equipment essential, preferably designed to produce extreme brief, closely spaced exposures in two planes simu taneously.

Angiocardiography is also useful over and b yond the study of central circulatory abnormaliti It is gratifying to be able to provide unmistakat

hronic Pyuria

iagnostic and Therapeutic Measures

C. D. CREEVY, M.D.
Minneapolis, Minnesota

HIS discussion is concerned, not with those mild acute infections of the urinary tract which appear completely with sulfonamides and forced ids, and never return, but rather with those ich become chronic or recur repeatedly. Failure simple therapy suggests that some factor is pro- ting the offending organism against the agents d, and demands a search for that factor before munization against all the potent antibiotics has curred. Only if this is done can crippling dam- e to the urinary tract be avoided in the majority instances. The neglected patient may suffer from urrent and disabling attacks of chills, fever, and sical irritation, or may lose a kidney from onephrosis; hypertension may result from uni- teral or bilateral cicatricial pyelonephritis; the tter may lead to death in uremia. Lithiasis may company a resistant infection with urea splitters, rticularly if urinary stasis is present.

The steps in the necessary investigation are well iown. In the female, the diagnosis of urinary fection cannot be made unless the urine is se- ired with a catheter; otherwise, a long and futile urse of chemotherapy may be directed against a uria which is actually vaginal in origin. In the ale, the starting point should be the two glass st. While this is indicative rather than conclu- e, a cloudy first glass with the second one clear ints directly to the urethra or prostate as the use of the pyuria. The prostate should always be assaged and the freshly expressed fluid examined der a cover slip for pus. While it is not very ten the source of a pronounced pyuria, the pos- bility should not be overlooked. If one finds areas tender induration in the gland, the possibility of ute prostatitis must be considered; this is a fairly mmon cause of recurrent dysuria and increased equency in the male. If the patient is examined tween attacks, the gland may feel normal, so that it may be necessary to have him return for a rectal examination during an acute attack in order to find the tender swelling which points to acute prostatitis as the cause of the symptoms.

The sediment of a centrifuged fresh specimen should be stained by Gram's method because the type of organism found (Gram negative rod or Gram positive coccus) is a rough guide to the selection of the proper antibiotic; and because complete absence of bacteria in the presence of pus suggests the possibility of amicrobic pyuria or of urinary tuberculosis. In this event, the urine should be cultured to make sure that the findings of the Gram stain are valid. One must remember that both the smear and the culture are unreliable if antibiotics have been given within the few days preceding the examination.

The next step is a plain roentgenogram of the urinary tract (KUB). One looks for stones, enlarged, shrunken, or absent renal shadows, for blurring of the margins of the psoas muscles (perinephritic abscess), and for lesions of bone.

The excretory urogram is invaluable as a rough screen for detecting abnormalities of the kidneys ureters, and bladder. Properly made, it will yield a high proportion of definitive diagnoses in surgical diseases of the kidneys and ureters, but is of limited value in recognizing small lesions of the bladder because the relatively large amount of contrast medium which accumulates will mask them. The urogram is particularly useful in urinary infections for estimating the relative functional capacity of the two kidneys; for determining whether suspected calcifications are within the urinary tract; and for detecting stasis and anomalies, i.e., hydronephrosis, vesical diverticula, ureteral duplications, et cetera.

The retrograde cystogram and urethrogram (often combined with advantage) are helpful chiefly when findings up to this point are negative but leave one with the feeling that something has been missed. For example, a radiolucent vesical calculus may produce a filling defect in the cystogram, an unsuspected diverticulum may be seen,

---

Presented at the annual meeting of the Northern innesota Medical Association, Bemidji, September, 955.

or a severe chronic prostatitis may appear as small irregular pockets protruding from the prostatic urethra.

No examination of the urinary tract is complete without a cystourethroscopic examination. Many blunders are due to failure to inspect the urethra, thus overlooking the typical fronds of a papillary urethritis in the female, and the dilated ducts with purulent secretion of a chronic prostatitis. Any proliferative lesion of the vesical or urethral mucosa must be subjected to biopsy, lest a small vesical neoplasm be overlooked or misinterpreted as inflammatory. Diverticula of the bladder too small to show in the cystogram (particularly one which is part of an excretory urogram) may be seen; specimens can be collected from each kidney to determine the source of a pyuria not otherwise localized; and retrograde pyelograms can be made when the urogram is unsatisfactory. One should not hesitate to repeat any part of the examination which leaves one with an unsatisfied feeling.

There are many factors which may prevent an infection of the urinary tract from responding to treatment. While these vary widely with age and sex, the principles involved in their recognition and treatment are the same. One should remember that stones and foreign bodies may fail to cause any pain whatever, and attract attention only because they incite and maintain infection. Even ureteral stones producing obstruction of considerable severity may be painless, and prostatic calculi rarely give rise to symptoms other than those of prostatitis. Large or branched renal stones are often painless. Vesical calculi and foreign bodies introduced during masturbation usually produce cystitis and pyuria without any symptoms suggestive of other lesions. For obvious reasons, children and adolescents who have inserted foreign materials into the bladder (chewing gum, paraffine, and candles are favorites) rarely admit it. These facts alone amply justify the employment of urography and cystoscopy in any stubborn infection. The latter is necessary because many calculi and most foreign bodies are radiolucent.

Congenital anomalies which lead to stasis of urine and so protect infecting organisms from therapeutic agents are numerous. Any hydronephrosis which develops gradually is likely to be painless except during bouts of acute infection; even then severe pain is rare. The commonest site of unilateral obstruction is the ureteropelvic junction due to congenital stricture, anomalous vessels, or peripelvic fascia. In the urogram one sees hydr nephrosis with a normal ureter. The horsesho kidney, while uncommon, is often the site of ob struction of this type. Duplications of the rena pelvis and ureter are rather frequently associate with hydronephrosis, usually due to ureteral na rowing. While this may be found at the junctio of the two ureters, it is usually located at the ves cal end of one of them. This may result from stri ture, from abnormal termination of the ureter the urethra or introitus, or from a coincident anomaly, ureterocele. Here the terminal ureter ba loons into the bladder because of a stricture whic involves only the mucosa of the ureteral orific This may obstruct one of a pair of normal urete on the same side or involve a single ureter; it ma overhang the vesical neck to such an extent as cause obstruction there, so that the resulting dilat tion of the upper urinary tract is bilateral.

Other congenital lesions causing urinary stas include vesical diverticula and anomalies produ ing obstruction at the vesical neck. A vesical d verticulum may cause stasis by retaining urin within it, by narrowing an adjoining ureter, or b compressing the prostatic urethra. Other disorde responsible for obstruction at the outlet of th bladder include flaps of mucosa overhanging th internal urinary meatus, congenital valves of th prostatic urethra, hypertrophy of the verumonta num, hypertrophy of the internal sphincter, an congenital absence of the abdominal muscles. In complete emptying of the bladders of infants an young children may also be due to defects o innervation of the bladder and to urethral stri tures and diverticula. Tragically enough, thes lesions are rarely recognized until the upper trac has been damaged beyond repair, simply becaus their possibility is not usually considered. Th situation would be much improved if physicia who take care of children would form the habit watching those with pyuria micturate, and checking the residual urine in every case of chron pyuria. The poor stream is an obvious sign obstruction or a weak detrusor. Only thus ca these serious disorders be discovered in time prevent hopeless deterioration of the kidneys.

Acquired diseases which cause stasis of urine a more frequent in older people. Commonest is pros tatism, whether benign hypertrophy, carcinoma or fibrosis. These foster infection only insofar they prevent emptying of the bladder or lead t the formation of stones. The former situation cognized readily by measuring the residual urine, d the latter by roentenograms of the bladder and cystoscopic examination. Next in frequency are obably urethral strictures. It is unfortunate that e striking reduction in the frequency of post-norrheal strictures which has accompanied the e of penicillin should be to some extent neu-lized by the increase of the traumatic variety e to accidents with the automobile and airplane, d in industry. While urethral stenosis predis-ses to infection by producing residual urine, the creased pressure required to force urine through e narrow area may dilate the prostatic ducts: if fection is present, these dilated ducts may be-me small abscesses: such lesions strongly resist edical treatment. They are most easily identified urethrography.

Diverticula of the urethra and of the prostate ay be congenital or may result from epithelializa-n of abscess cavities. Their presence leads to asis within their lumina, so that infection is stered. and stones may form as water is absorbed, aving urinary salts behind. Such diverticula are ever discovered unless the physician remembers to ok for them. They are best demonstrated with e urethrogram.

Localized proliferative or fibrotic inflammatory sions are fairly common sources of persistent or current infections. Most frequent are the papil-ry or polypoid masses which develop at the inter-al urinary meatus in the female. They probably sult from a combination of circulatory disturb-nce incident both to relaxation of the pelvic floor nd to postpartum scarring, with bacterial inva-on. During an acute attack these proliferative ructures swell, giving rise to a desire to micturate ecause of their presence within the first portion of he urethra. Since they cannot be expelled, the esire persists or soon recurs because of the feeling hat there is something in the urethra. Acute at-acks are associated with pyuria and bacteriuria, nd are usually mistaken for "cystitis." The epi-odes subside with antibiotics, but the papillary tructures remain as areas of lessened resistance, nd almost invariably give rise to subsequent at-acks. Some will disappear with weekly dilatations f the urethra to 30 or 35 French, followed by the opical application of ½ to 1 per cent silver ni-rate; many will require electrocoagulation through he urethroscope.

Cicatricial urethritis (simple fibrosis of the rethra) may cause contracture with obstruction to urination and, consequently, residual urine, and so lead to recurrent infection. For this reason, every woman with chronic or recurrent urinary infection should have the residual urine measured. Weekly dilatations of the urethra after the active infection has subsided will often so improve emptying of the bladder that the pyuria disappears. Failure of the dilatations to bring relief suggests obstruction at the vesical neck, diverticula (quite rare in the female) or neurogenic dysfunction.

Cystic lesions of the vesical mucosa (cystitis cystica) are usually the result rather than the cause of recurrent infections. Occasionally they may become so numerous and so large that it is desirable to destroy them by electrocoagulation.

Recurrent pyelonephritis may cause so much scarring as to impair local blood supply, and so leave the kidney vulnerable to future attacks. Such lesions cannot, of course, be cured. Occasionally they may cause hypertension, which may disappear after nephrectomy if the renal disease is unilateral. When it is bilateral, we must be content with treating the individual attack with antibiotics, not forgetting to explain to the patient the reasons for our inability to prevent recurrences.

One must always remember renal tuberculosis when dealing with unresponsive infections. While pyogenic organisms are not ordinarily found in the urine in tuberculosis (to the extent that a sterile urine culture in the presence of pyuria always brings up the question of tuberculosis), secondary infection may occur even with chills and fever, and so delay recognition of the underlying disease. This is one of the cogent reasons for making urographic and cystoscopic studies in every resistant infection. Careful search for the tubercle bacilli by means of the acid fast stain, guinea pig innoculation and culture will invariably reveal the organism if one persists long enough, but pyelograms should be made before delay has permitted the renal tuberculosis to progress or allowed secondary vesical tuberculosis to cause fibrosis of the bladder.

One cannot honestly say that an infection persists or recurs due solely to bacterial resistance to antibiotics and urinary antiseptics, until careful urography and cystoscopy have demonstrated the absence of the disorders already described, because almost any pyogenic organisms can acquire resistance when attempts are made to eradicate it with antibiotics without correction of the predisposing lesion. Therefore, one should not take the results of sensitivity tests indicating resistance as final without careful and perhaps repeated review of the whole urinary tract. The strains of bacteria most often resistant to drugs are Bacillus proteus, Aerobacter aerogenes, and Pseudomonas aeruginosa, although almost any pathogen may become resistant in some circumstances. Sensitivity tests make a good starting point with antibiotic resistant bacteria. While scientific studies require the use of the serial tube dilution method, this is not necessary for ordinary clinical purposes. One can use Petri dishes containing blood agar, and divide the under surface into labelled quadrants with a wax pencil. Fresh urine collected with sterile precautions is smeared on the agar. "Difco discs," each saturated with an antibiotic to be studied, are dropped onto the agar, taking care that each one corresponds to a labelled segment. Organisms can be classified as resistant if, after twenty-four hours in the incubator, they have grown right up to the edge of the disc. They may be classified as slightly, moderately, or quite sensitive according to the width of any clear zones of inhibition around the discs. While correlation will be far from perfect, the results are useful clinically.

In general, B. proteus is unlikely to respond to any one antibiotic, but many strains will succumb to a combination of two, or to an antibiotic combined with an urinary antiseptic. Combinations likely to be effective include penicillin and streptomycin, Chloromycetin and Gantrisin, and Furadantin and Gantrisin. The first pair has, of course, to be injected intramuscularly. Relatively large doses should be used, say 500,000 units of penicillin and 0.25 gram of streptomycin every four hours. Because of the tendency of the latter to provoke both reactions and bacterial resistance (or even dependence), the course of treatment should be short. More convenient to use and just as likely to be effective are Chloromycetin 0.5 and Gantrisin 2 grams four times daily; at the end of a week the dose is reduced to one half; after another week it is cut to one quarter of the original level, being stopped at the end of the third week. However, if the urine is not grossly clear at the end of the first week, there is no point in continuing this regimen. The third alternative consists of Furadantin 7 milligrams per kilogram of body weight per day divided into four equal doses, and Gantrisin 2 grams four times daily. The former should never be taken on an empty stomach; nausea from the first few doses may disappear if administration is continued. The same practice of halving dose at the end of the first week, and of quarte it at the end of the second is followed; it is stop at the end of the first week if the urine has cleared. The object of the continuing the regir for three weeks is to kill all of the organism possible, since there seems but little doubt many recurrences are due to stopping treatmen soon as the urine clears; the ability of the org ism to grow may be only temporarily impaire this point.

Pseudomonas aeruginosa is usually insensitiv all of the antibiotics ordinarily used, althoug few strains may succumb to one of the tetr clines or to calcium mandelate in adequate d (3 grams four times daily with the fluid int limited to 1200 cubic centimeters). While in tions with these organisms are rarely serious, an casional strain may behave in a highly viru fashion. Here one uses Aerosporin (polymyxin Because of its neuro- and nephrotoxic proper and because it has to be given parenterally, patient should be hospitalized. The drug is mi with 1 per cent procaine and injected intramus larly. Even then, it may cause pain at the site injection. The largest safe dose is probably milligrams per kilogram per day in four equ divided amounts. If treatment is continued more than a few days, the renal function should checked every forty-eight to seventy-two ho while keeping alert for signs of damage to central nervous system.

Aerobacter aerogenes is a close relative of coli, but is far more resistant to antibiotics than latter. Agents most likely to be effective are tetracyclines, chloromycetin, and sulfonamides, that order. Streptomycin may be successful; viously the sensitivity tests are useful here, as as in resistant strains of other species.

Staphylococci which are resistant to penici may succumb to erythromycin, 400 milligrams f times daily. Formerly, the intravenous injection neoarsphenamine or mapharsen in small, frequ doses could be counted upon to cure a few st born chronic infections, but the success of peni lin in the treatment of syphilis has resulted in virtual disappearance of the arsenicals from market. This is particularly regrettable in admittedly rare amicrobic pyuria, which was w to vanish like magic following the use of th agents.

oentgenographic Findings in Respiratory roblems of Infants

S. B. FEINBERG, M.D.
Minneapolis, Minnesota

THE acute respiratory problem of the neonatal period is one which often requires rapid diag- osis to insure proper therapy. The gradually eveloping lesions can be handled more leisurely; evertheless, both the acute and chronic lesions ave roentgen findings which will frequently aid e clinician in diagnosing the case. The clinical nd roentgen findings together will be of more alue than either one alone. These entities will e discussed in the order in which they might be ncountered during neonatal and early childhood periods.

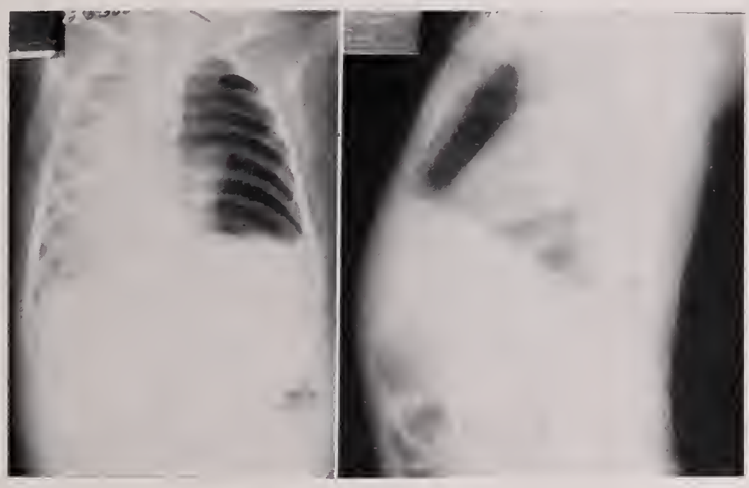

Fig. 1. (Case 1) A five-day-old white male child who had acute respiratory distress from birth. Diagnosis: crush type hydropneumothorax with shift of the heart and mediastinum.

Birth trauma frequently results in an asymptomatic pneumothorax, especially in the premature infant. Only those cases which have marked collapse of the lung with resultant respiratory distress are examined radiographically. Fractured ribs are rarely found. The development of the pneumothorax is usually due to a crush injury which is the same in infants and adults. Simple alveolar rupture into the pleural space or retrograde passage along the perivascular tree to the hilar root, free pleural space, mediastinum, and subcutaneous tissues[1] are the two routes for the passage of air (Fig. 1).

Aeration and expansion of the lungs are gradual processes especially in premature infants. When the process of inflation fails to occur, which is thought to be on an obstructive basis by some,[2] various degrees of distress, cyanosis, and even death will follow.

Farber and Wilson[3,4] have shown that there is physiologic atelectasis of varying magnitude during the first four days of life in full-term infants who have no respiratory distress. In contrast, the premature infants' lungs may not fully expand for from four to six weeks. They feel that cohesive forces, faulty or ineffective function of the respiratory centers and an underdeveloped thoracic cage are more important in the failure of expansion in primary atelectasis than is true obstruction, which has been postulated as the cause of fetal atelectasis.

A problem which is particularly interesting to us at the University of Minnesota Hospitals is that of hyaline membrane disease. It is not found in stillborns or within the first hour of life.

From the Department of Radiology, University of Minnesota Hospitals.

Lungs are the poorest developed organ at birth and have to take on an entirely new function at birth.[5] At the four- to five-month stage of gestation. gas exchange would be impossible. The respiratory tree is lined by cuboidal cells which separate the blood vessels from the potential air space. If the infant were born at this stage, the cuboidal cells would prevent passage of air. At the fifth month, capillary buds begin to push the epithelium aside and are exposed to potential air spaces. By the seventh month, sufficient capillaries are exposed to sustain life. Anything which interferes with this process is a hazard to life, which accounts for more difficulty in prematures.

In hyaline membrane disease. the infant will usually breathe spontaneously. Later, the respirations become labored and are accompanied by retraction of the thoracic wall. Occasionally there is recovery, more often death occurs in forty-eight hours. Grossly the lungs are dark red and firm and sink in water. Capillary engorgement is a microscopic finding. The major alveoli and respiratory ducts are collapsed. The few remaining air spaces are lined with a hyaline membrane.

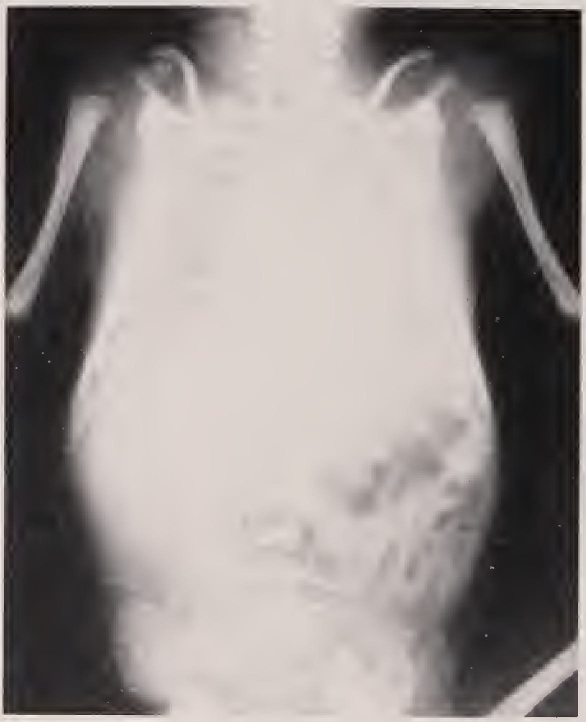

Fig. 2. (Case 2) A premature with respiratory distress at eight hours at which time retraction developed. Radiographs and thoracotomy showed atelectatic changes compatible with the diagnosis of hyaline membrane disease. Autopsy showed secondary atelectasis with hyaline membrane lining of many alveoli.

The exact etiology is unknown. Aspiration amniotic fluid has been considered as the cau for many years.[6,7] This view has been challenged,[8-] and the role of capillary exudation and other bi chemical factors must be considered.

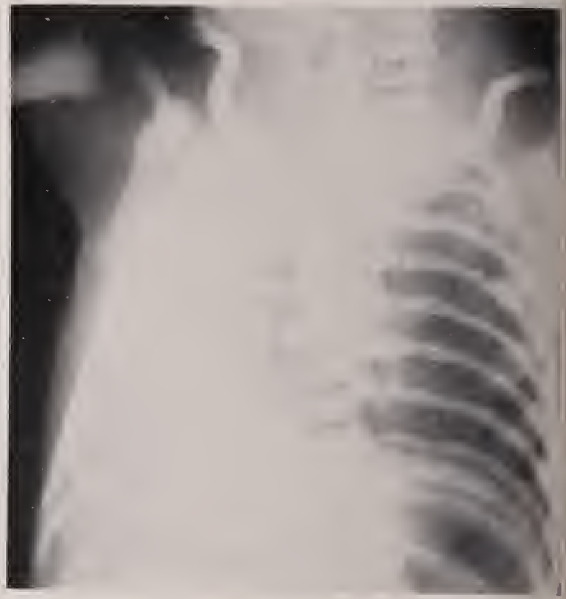

Fig. 3. (Case 3) A one-day-old female child who ha a tracheoesophageal fistula. There was also respirator distress thought to be due to aspiration pneumonit and/or atelectasis. Chest study showed shift of the hea and mediastinum to the right with compensatory emph sema on the left. A differentiation between agenesis an atelectasis had to be made. Autopsy findings showed th fistula, agenesis of the lung, and aspiration pneumoniti

The roentgen findings have been described[12-] as ranging from generalized granularity or nodu larity, to complete atelectasis with or without pe ripheral emphysema (Fig. 2). At present, we ar attempting a study to follow the roentgen evolu tion of the disease more closely.

Not all respiratory problems of infants are du to bizarre causes. Most cases involve simple pos partum pneumonitis[15] or aspiration. One must als consider the possibility of an underlying anomal such as a tracheo-esophageal fistula with secondar aspiration, atelectasis, or both. Likewise, pulmo nary anomalies, such as agenesis of the lungs, ma be misinterpreted as an acquired disease (Fig. 3 Bronchography and planigraphy are necessary t confirm the diagnosis.[16] Infantile myasthenia grav may show swallowing problems with secondar aspiration and pneumonia. We must also acknow edge the congenital diaphragmatic hernia as a occasional cause of neonatal respiratory distress a esult of compression of lung parenchyma by the rathoracic location of abdominal viscera.

As described by Henry[17] and Van Epps,[18] hypert phic lobar emphysema is an acute respiratory oblem found primarily in the new born. Dyspnea d cyanosis often develop within a few days of rth. No infectious disease is present (Fig. 4). arious causes for the finding have been listed, ch as, redundant bronchial mucosa acting as a eck valve, abnormal cartilagenous ring development, aberrant vessel compression, and a stenosed onchus. Some cases have no discernible bronial lesions. The lungs are overdistended and aparently quite pink. They remain distended after moval, suggestive of an elastic tissue abnormality.

The course is one of a normal infant who bemes dyspneic with or without cyanosis shortly fter birth. On examination they have classical mphysematous findings with no evidence for inammation. The signs and symptoms are more larming than in cases of true cysts. Radiologic ndings are those of localized lobar distribution of mphysema, manifested by a large translucent zone onfined to a lobe with adjacent compression, ediastinal shift, and compensatory herniation. he septa of cystic disease are absent. Johns[19] xpressed the opinion that all non treated cases ied. Caffey[20,21] described spontaneous regressions. The decision to excise the lobe depends on the degree of hypoxia and respiratory embarrassment.

Cystic disease, either congenital or acquired, must be differentiated from lobar emphysema. In the obstructive cyst, tension pneumothorax must be excluded.[16] Whether closed or open, these conditions are not recognized early unless they become infected or compress much lung parenchyma. The closed cysts may be fluid filled and as a result are not radiographically translucent. The air filled pneumatocele, by contrast, will cause various degrees of translucent replacement and displacement of lung parenchyma, sometimes simulating a tension pneumothorax with shift of the heart and mediastinum to the opposite side (Fig. 5). There may be associated circulatory compression.[22] Septa are a diagnostic feature in this entity. Post inflammatory pseudocysts can produce similar clinical findings, but they do not involve alveoli or bronchi[23] (Fig. 6).

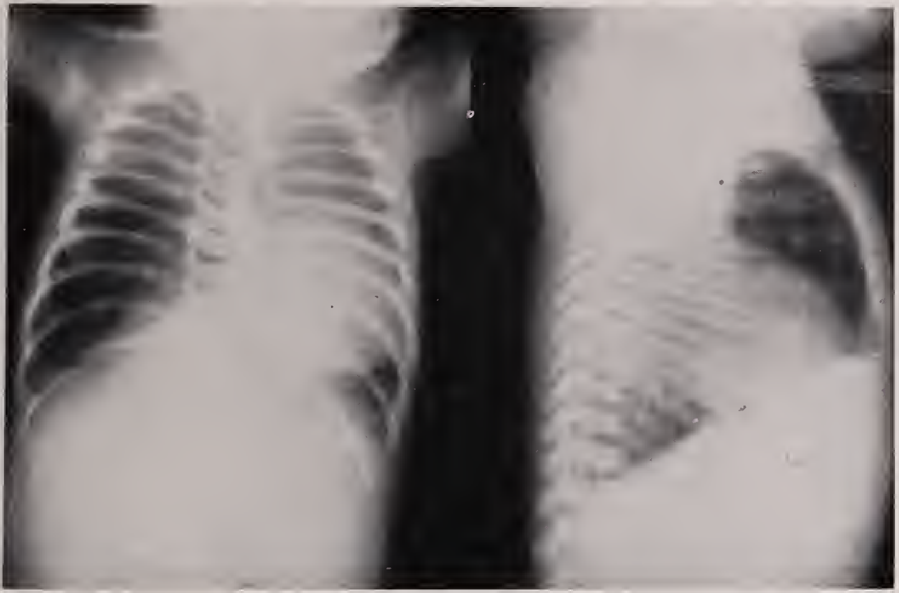

Fig. 4. (Case 4) A seven-day-old female child who had marked respiratory distress and cyanosis from the third day. X-ray showed mid lung field emphysema and compression atelectasis of the right upper and lower lobes. Impression: hypertrophic lobar emphysema. (Surgery—lobectomy confirmed the diagnosis.)

Figure 4 is presented through the courtesy of Drs. Roger Lienke and E. F. Van Epps, University of Iowa, and by permission of the publishers of *The American Journal of Roentgenology, Radium Therapy, and Nuclear Medicine.*

The histological differentiation between congenital and acquired cysts is difficult. Condon[24] has shown that respiratory epithelium responds rapidly to injury and that epithelial linings *per se* are no index to the congenital nature of the cyst.

Methemoglobinemia[25] due to ingestion or absorption of various chemicals such as nitrites, ace-

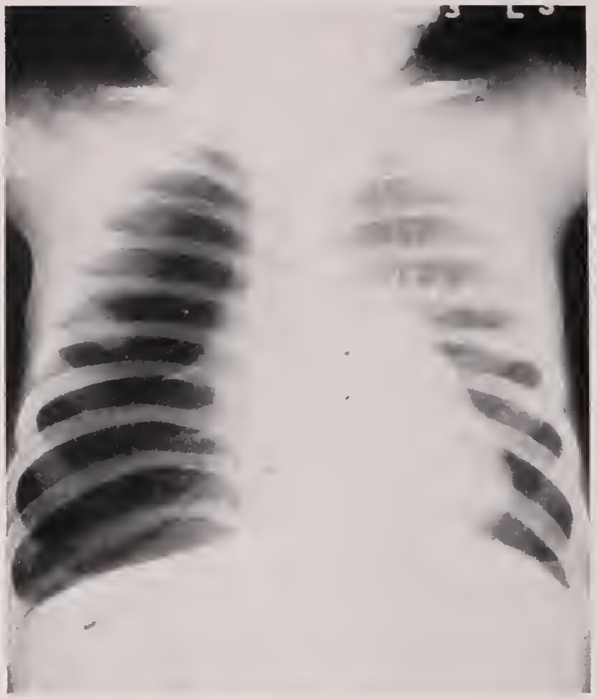

Fig. 5. (Case 5) A two and a half year old boy who tired easily but a lesion was not discovered until nine months of age when an x-ray was taken. There was marked lung field translucency with compression of the heart and mediastinum to the left. Septa were present. Diagnosis: cyst. Surgical and pathologic diagnosis: congenital cysts.

tanilid, potassium chlorate, nitrobenzol, etc., r sults in the formation of an oxyhemoglobin which the oxygen is firmly bound and which dc not function in respiratory exchange. As a resu cyanosis is the presenting finding with dyspne Congenital heart disease is often suspected. V recently had a patient who was clinically suspect to be an example of tetralogy of Fallot. Radi graphically there was questionable increase in lu field translucency. The cyanosis cleared after o day of hospitalization in the Heart Hospital, and was found to be due to a high concentration nitrites in well water. The outcome of this ca was fortunate, but the disease can be fatal if n recognized. Actually there are no diagnost roentgen findings.

Arteriovenous aneurysms[26] are another cause f cyanosis in the infant even though the lesions a usually discovered later in life (Fig. 7). If tl shunt is large enough, cyanosis can be recognize early. The usual later findings are clubbing of tl fingers, exertional dyspnea, cardiac strain, and se ondary polycythemia. A bruit is sometimes hear over the area. Due to shunting of the bloc through the malformation, there is often a d creased parenchymal vascular pattern. In the are of the lesion, a serpiginous shadow radiating fro the hilum is the expected finding. Often, these a

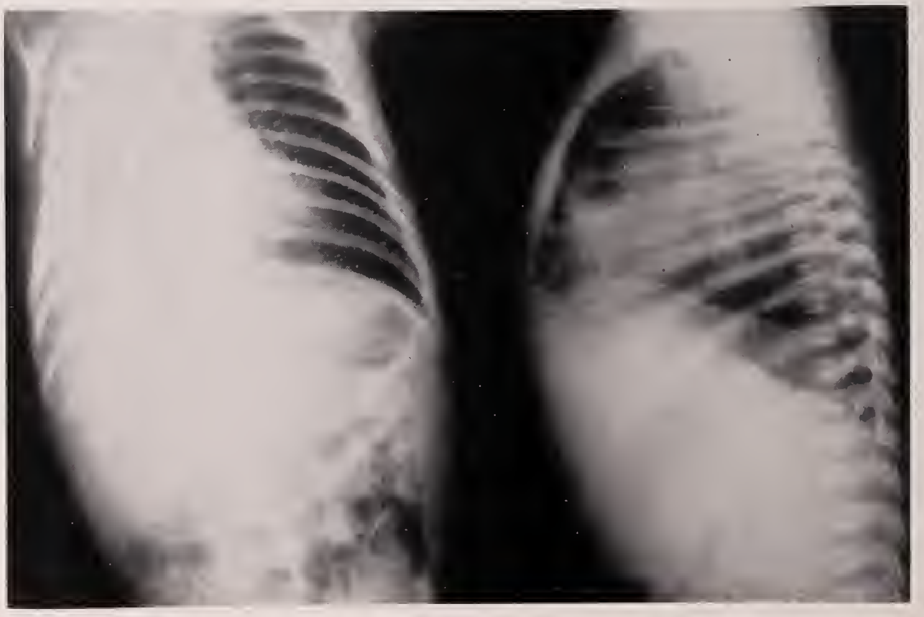

Fig. 6. (Case 6) A one-month-old boy who developed aspiration pneumonia after a herniorraphy on the first day of life. This was followed by effusion and post aspiration empyema. The empyema loculated anteriorly and was followed by anterior cystic lesions of the interstitial, extra-alveolar pseudocyst variety.

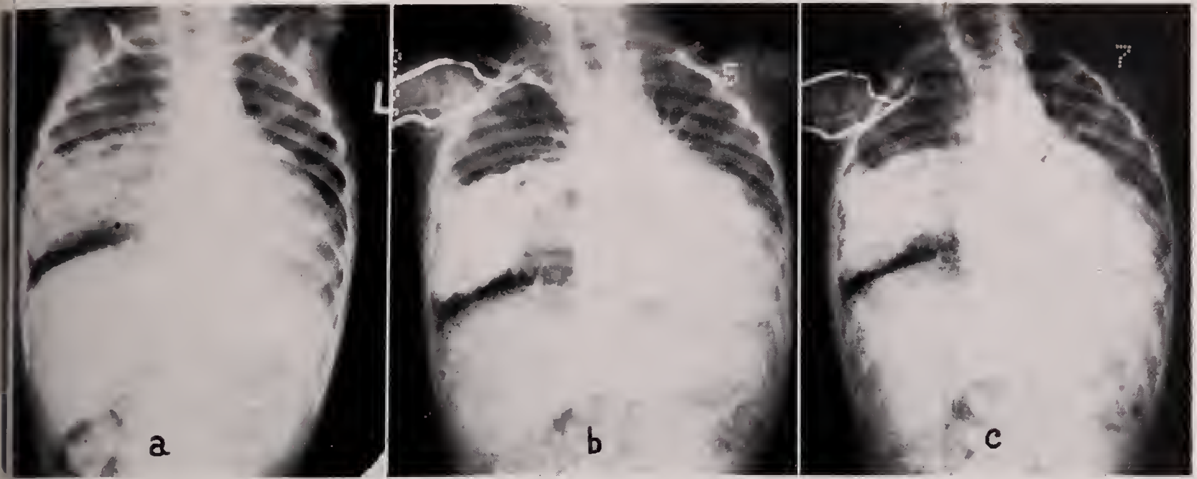

ig. 7. (Case 7) (a) Male child born in a tuberculosis sanitarium was not seen by mother until two months, d she wasn't aware of cyanosis until nine months. The right middle lobar patchy density had a central cluster sharply circumscribed densities suspected of being an anteriovenous aneurysm. No bruit was heard. (b and c) An-gram confirmed the diagnosis. Surgery confirmed the finding but the child died of cardiac decompensation and ma.

ltiple with smaller defects that do not become parent until the obvious lesion has been re-oved.

Summary

Many pulmonary problems which present with spiratory distress and cyanosis in the neonatal riod and infancy have been discussed and their entgen manifestations demonstrated. The com-nation of clinical, radiologic, and laboratory dies will often lead to the correct diagnosis and eatment.

Electrolyte Disturbances in Dehydration

WILLIAM M. WALLACE, M.
Cleveland, Oh

THE successful and definitive repair of dehydration and its accompanying abnormal states of acid-base equilibrium depends more upon the kidney and the cybernetic mechanisms controlling its function than it does upon the acumen of the clinician in selecting the type and quantity of fluid to be administered. The history of parenteral fluid therapy is replete with eponymic solutions of great diversity and complexity, all of which have been used with surprising success to restore the volume and composition of the body fluids. As the sophistication of technique progressed, the view of the underlying mechanisms upon which rational and intelligent therapy could be carried out was lost. Talbot, Crawford and Butler[1] have rendered the good service of reminding us of the items just noted and have pointed out the corollary that, if the body is offered quantities of water and ions within the ability of the kidney to conserve or reject these substances, a proper sorting out will occur and normality will be quickly restored. One major difficulty seems to fall in the way of giving the kidney all of the responsibility for therapy. At times it may not be working properly, either for reasons of its own or because its communication system has gone awry. In about eighty out of a 100 instances, routinized therapy for dehydration and its associated ionic disturbances will work admirably and produce the desired results. In a few of the remaining twenty instances, no therapy will be successful as the physiologic pathology will have gone so far as to be irreversible. In other instances the deficits are bizarre or the homeostatic links required for adequate renal control are broken. Therapy in this same group, if it is to be successful, must be based on understanding of mechanisms. The use of formulas and tables will fail. Clinical observation and reflection will often serve to identify the patient in whom normal homeostatic mechanisms will fail to aid therapy. At times failure to respond to standardized forms of therapy may give the clue that the situation is unusual one.

Figure 1 indicates the idealized homeosta mechanisms by which the organism postpon death from circulatory failure as water depriv occurs and progresses. It should always be bor in mind that the basic cause of death in dehydr tion is reduction of blood volume below a critic point where circulation fails. While the diagra is constructed to indicate the events occuring pure water deficit (man in the desert), it for the basis for critical thinking about what happe to the patient who, in addition to being unable take or retain water by natural means, suffers fro deficit of renal, adrenal or pituitary function from wasting of body electrolyte.

The diagram is best understood by followi down the two sides simultaneously until the fin credit for the whole transaction has run out, ar the debit is ready for therapy. Once water inta stops, from whatever abnormal cause, deficit in mediately results because of the continuous obli atory loss of water from the skin, lungs and ki ney. The process is analogous to the boiling aw of water from a pot on the stove. Loss of wat can only be stopped by putting out the fire. water thus leaves the body, the volume of extr cellular fluid (ECF) is first to decrease. Simu taneously, as indicated on the right side of t diagram, the factors of infection, trauma, pai and fasting lead to increased ACTH productio by the pituitary. The increased ACTH resu in production of the catabolic adrenal hormo hydrocortisone. Decreased ECF (or blood vo ume) appears to directly stimulate the productio of the sodium retaining adrenal hormone aldo terone. This sequence is indicated by the arro across the top of the diagram. The question ma breaking the arrow indicates lack of comple experimental proof of the sequence. Decrease body sodium or increased body potassium ma also be factors. Returning to the left side, we s that, as volume falls, the osmotically active solut mainly sodium and chloride, of the ECF tend t rise. This increase in concentration is accentuate

Presented at the Fall Meeting, Northwestern Pediatric Society, Bayport, Minnesota, September 23, 1955.

t the renal retention of sodium secondary to the ect of aldosterone on the renal tubule. The rise i concentration of sodium in the plasma leads to s rction of antidiuretic hormone (ADH) by the sterior pituitary as has been so beautifully shown Verney.[2] In turn, ADH leads to maximal wa- reabsorption by the kidney as indicated by ximum specific gravity of the urine. A sec- d consequence of the increased sodium concen- tion is the transfer of intracellular water to the F in response to the now imbalanced osmotic essure. Transfer of water is further aided by the tabolic effects of hydrocortisone secreted in re- nse to the stressful stimuli. Under such hor- onal actions the individual, in effect, "self-feeds" mself from his own body substance. Potassium d nitrogen are lost from the cell and water and lories become available. Aldosterone again steps to the homeostatic chain by facilitating the re- l excretion of potassium and preventing a lethal e of this ion in ECF.

The events just described allow the ever-increas- g deficit of ECF to be shared by the relatively uch greater volume of intracellular water. Fur- ermore, as long as homeostasis succeeds, little ange in electrolyte concentrations will occur. dium, potassium and nitrogen (urea) concen- ations will be normal. As Gamble[3] has pointed it, these mechanisms greatly multiply survival me under water deprivation. Without these echanisms for spreading water deficit over all e body water, the circulating fluid volume would e quickly wiped out.

Changes in the plasma concentration of sodium, otassium and urea should indicate to the clin- ian that the ultimate strain has been placed on e mechanism or that somewhere the process is ot working properly. If the adjustments have een perfect, the only abnormality will be reduc- ion in volume of the body fluids and net loss of xtra-and intracellular electrolyte. In very general erms we know that when 10% of the body eight has been lost as water, the final strain be- omes evident in the form of peripheral circula- ory failure and beginning distortion of the ECF onic pattern.

Modern concepts of fluid therapy are designed o reverse and take advantage of the sequences ust described. The initial attack is made upon estoration of circulating volume by means of arious facsimiles of ECF varying in sophistication rom "normal" saline to lactated Ringers solution. Simultaneously, or very closely thereafter, provision must be made for the obligatory expenditure of water from skin and lungs and for water to relieve the kidney of the burden imposed upon it by ADH and the need for excretion of products of cell breakdown. This combined operation is accomplished by the administration of solutions containing one-third to one-half the concentration of electrolyte contained in so-called "normal" saline. Reflection about the sequences shown in Figure 1 will indicate that the practice of infusing saline solution or saline in glucose alone in dehydration does little but accentuate the disturbance. The ill effects of fluid volume deficit may be temporarily overcome but any gain is quickly offset by the subsequent accentuation of abnormal plasma electrolyte pattern. Success in treating dehydration with isotonic saline in the past indicated that the extraordinary fortitude of the kidney coupled with the fact that restoration of circulating volume revived the patient sufficiently so that he could drink naturally occurring hypotonic fluids. With present-day knowledge it is better not to gamble on these possibilities.

Once the threat or actuality of circulatory failure has been removed and the kidney "primed," the beginning of repair of the intracellular fluid may be carried out by provision of potassium in the administered fluids. If potassium is not provided, sodium ion will take its place in intracellular fluid. This latter occurrence, if of the usual limited degree, seems of no clinical significance but if extensive, produces clinical symptoms.[4,5] Provision of potassium in parenteral fluids is generally only necessary when a prolonged period (two days or longer) of parenteral fluid therapy becomes necessary.

In a certain small number of patients the homeostatic mechanisms will have failed and cannot be depended upon to aid in therapy. Clinical observation and intelligent use of the laboratory will serve to identify these patients and to guide therapy. It is obvious that any break in the mechanisms shown in Figure 1 will prejudice operation of the whole system. The clinically most common examples are abnormal extrarenal loss of sodium salts or failure of the kidney to conserve them. Loss of sodium through diarrhea, vomiting suction drainage, sweating, diuresis or failure of the renal sodium conserving mechanisms allows ECF sodium concentration to fall as water deficit increases. As a consequence, ADH secretion fails to occur as does osmotic transfer of water from intracellular fluid. The brunt of dehydration falls on the ECF alone, and the critical point in reduction of circulating volume is reached in hours rather than days. The patient with adrenal insufficiency is the rare but pure prototype of such a failure of homeostasis. So-called "base-losing nephritis" and instances of suction drainage without adequate electrolyte replacement are more common examples. Patients with salt depletion in excess of water can often be clinically identified. Signs of peripheral circulatory failure are profound, blood pressure is low and pulse rate high, skin turgor is decreased to an exaggerated degree, and the traditional Hippocratic facies are present. Physical examination shows a generalized muscular hypotonia. Unless the condition is far advanced, the sensorium is clear and the psyche seems dominated by alternate lassitude and anxiety. The plasma sodium concentration is low and potassium and urea high. The routine administration of hypotonic potassium-containing solutions to such patients accentuates the clinical and chemical disturbances and results in deterioration of the situation. Such patients are, in effect, suffering from water i toxication. Their initial therapy must be wi isotonic solutions of electrolyte, not hypotonic. the severely ill patient with dehydration treat pragmatically with hypotonic solutions, caref watch should be kept in the six to eight hou following initiation of intravenous fluid therap If the typical favorable response does not follo in this period, the suspicion of hypotonic dehydr tion should be raised, and therapy should changed to that with isotonic solutions of electr lyte. Correlation of the clinical state with mea urement of the serum sodium or chloride conce tration is invaluable at this point.

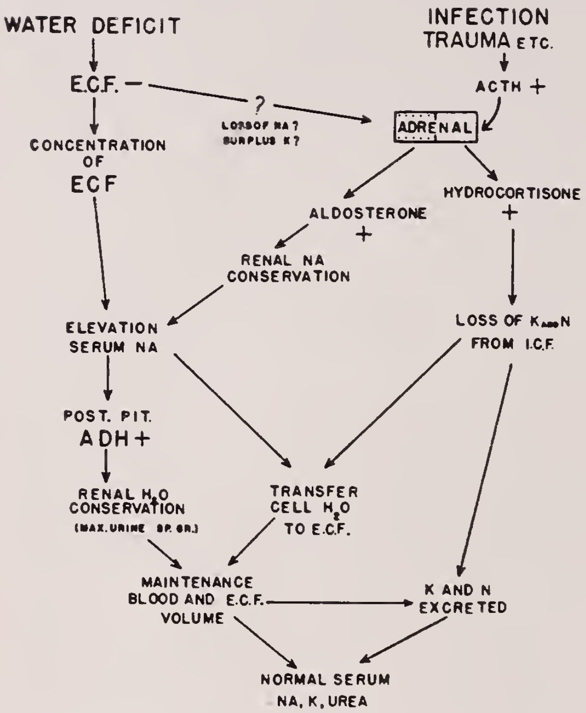

Fig. 1. Schematic presentation of the homeostatic mechanisms acting during water deficit. + or — signs indicate that a function is increased or decreased. E.C.F., extracellular fluid; ADH, antidiuretic hormone; I.C.F., intracellular fluid. For explanation see text.

In a goodly number of instances of dehydratio particularly in infancy, the homeostatic mecha isms seem to have over-reacted to the stimulus dehydration. Sodium retention by the kidney h been intense, and the expenditure of water witho salt from the skin, lungs and intestinal tract u duly high. The situation is crudely analogous that of a beaker of saline solution boiled to ne dryness over a flame. The concentrations of s dium and chloride in the plasma are far abo normal. The dehydration may be termed "hype tonic." Again, good clinical observation will ide tify many of these infants. Their appearance nearly the opposite of those with low sodium co centrations. Signs of circulatory failure are min mal; skin turgor is deceptively normal, and th eyeballs are not sunken. Unlike the patient wit salt depletion and dehydration, they are out contact with the environment. Their extremiti and back are stiff or even rigid, and the examin gains the impression that they are close to th convulsive point. Often this is true. In infan the initial mistaken diagnosis of meningitis is ofte made, and the water defict ignored. If sought, lab oratory signs of central nervous system damage a usually found. Spinal fluid proteins are near always increased and the EEG abnormal. Figu 2 shows the initial EEG tracing in an infant who serum sodium concentration reached the rath astounding value of 200 mEq./l. as a result dehydration secondary to gastroenteritis. Eig days later, after appropriate therapy, the traci is normal. Usually the lesions seem function and reversible, although in a few instances th presumed chemical trauma seems to be permanen Abnormally high concentrations of serum sodiu are frequently encountered in patients with pri central nervous system disease.[6] Time does n

ow complete discussion of the pathologic phy-
slogy of this type of dehydration. This can be
und elsewhere.[7,8,9] Suffice it to say that the
int of the water deficit has been borne by the
racellular rather than the extracellular fluid.
tracellular volume seems to be relatively intact.
ss of potassium does not seem to occur. Ionic
ncentrations within cells, like extracellular con-
itrations, are high.

The question may be asked as to the relative
quency of abnormal states of ionic concentra-
n in dehydration. In a two-year period at Babies
d Children's Hospital of Cleveland, 220 out of
00 admissions were instigated with dehydration
an urgent diagnosis. In seventy-seven instances
asurements were made of the serum sodium
ncentration before therapy was initiated. Seven-
per cent of the seventy-seven were in the normal
nge (130 to 150 mEq./l.); 20 per cent of the
ncentrations were over 150 mEq./l., and 10 per
nt under 130 mEq./l. Presumably the majority
oup had come along the path of dehydration
th normal homeostatic mechanisms in operation.
the majority group a single parenteral solution
th an electrolyte concentration of 50 to 70
Eq./l. would serve for ideal repair. In the re-
aining patients individualized therapy based on
inical observation supported. if possible, by labo-
tory measurements would be essential for effec-
ve therapy.

Before concluding, note should be taken of the
id-base disturbances that inevitably accompany
hydration. They are the result of differential
sses of cation (base) and anion (acid) in intes-
nal fluids and urine coupled with the increased
quirement for anion excretion occasioned by the
estruction of tissue outlined above. Correction of
ese disturbances depends upon restoration of cir-
ulatory efficiency and the consequent return of
nal function. Correction of the acidosis by infu-
on of alkaline solutions should be a strictly sec-
ndary consideration in planning therapy. The
istory of parenteral fluid therapy supports this
ntention. The earliest attempts at the begin-
ing of this century to understand and study the
athologic physiology of diarrheal disease centered
bout the finding of acidosis in the blood of these
atients. At that time little understanding existed
ncerning the volume and composition of the
ody fluid compartments and their critical rela-
onship to circulatory and renal function. Thera-
eutic efforts centered around the administration of strongly alkaline solutions in small volume. Such procedures increased mortality and were soon abandoned. Some years later Hartman pointed out the therapeutic efficacy of combined procedures to restore both the volume and the ionic composition of the body fluids.

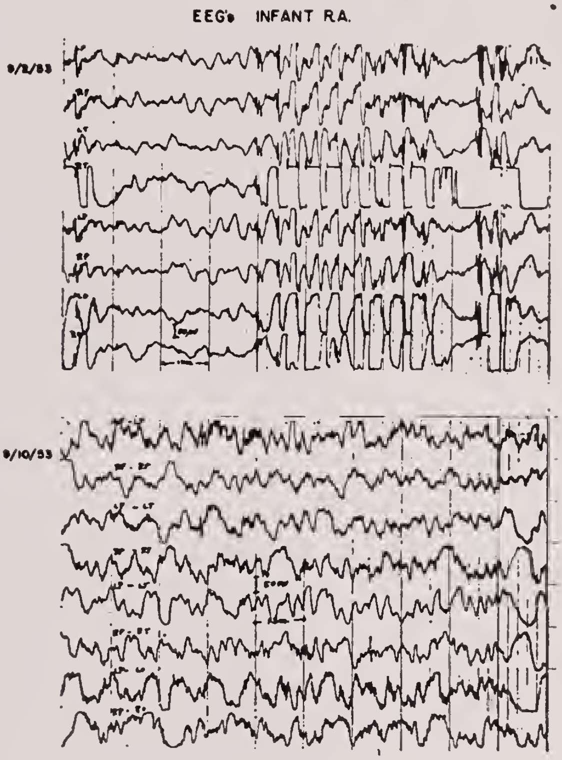

Fig. 2. Electroencephalogram of a 6 months' old child with severe hypertonic dehydration. The tracing at the top was made when the serum sodium concentration was 200 mEq/l. The lower tracing, 8 days later, was made at recovery.

Summary

The homeostatic mechanisms utilized by the body to defend itself against dehydration have been described. The central role of these mechanisms is to sustain for the longest possible period of time the circulating volume and composition of the body fluids. In disease these adaptive mechanisms may fail. The clinical signs indicating such failure and their correlation and corroboration with and by laboratory measurements are discussed. Therapy of dehydration is discussed in light of these concepts.

Seminar

THE PYRROL PIGMENTS AND HEMOGLOBIN CATABOLISM

C. J. WATSON, M
Minneapolis, Minnes

THERE is a singular merit in the establishment of an E. T. Bell lectureship by the Minnesota Pathological Society. Dr. Bell has nurtured this society from its neonatal period. His guiding hand and penetrating wisdom, mellowed with his delightful sense of humor, have been mainstays of the society these many years. As one of his former and, may I say, continuing students for many years, it is a special privilege for me to give this first E. T. Bell Lecture.

I thought it might be appropriate to discuss a topic in which I became interested nearly thirty years ago, while a member of Dr. Bell's department. The general character of the advances in that interval of time depends, of course, upon many factors, among which may be mentioned a greatly augmented knowledge of porphyrin and bile pigment chemistry gained in part by older, classical methods. The more recent advances in this area rest on many new techniques, especially the application of the chromatographic method and the utilization of isotopic tagging. Some of the most significant advances were enabled by the discovery of Shemin and co-workers[1,2,3] that glycine and acetate are the essential building blocks of the porphyrin and bile pigment molecules. This, together with Westall's isolation of the monopyrrolic precursor, Waldenström's porphobilinogen,[4] and subsequent studies of intermediary substances, has provided clear insight as to the anabolic aspects of hemoglobin (heme) metabolism. While this is not the topic that I shall devote the most time to, it is desirable to comm briefly on the main facts that have now emerg in order that anabolic and catabolic pathw may be in some measure compared.

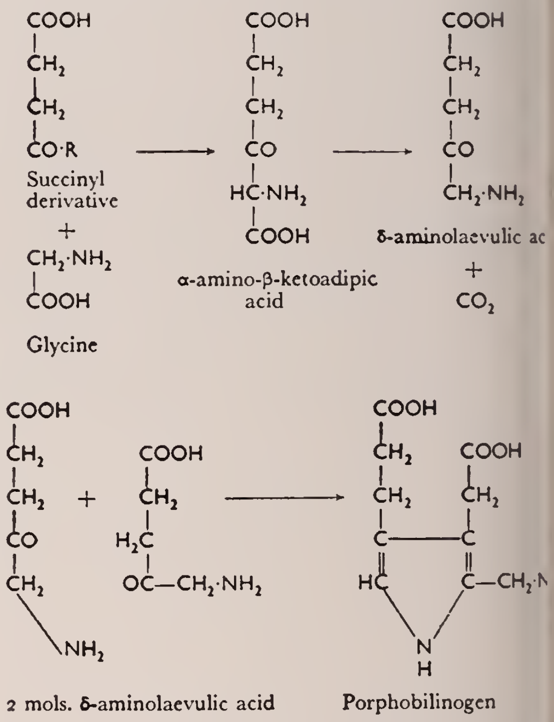

Fig. 1. Stages in the biosynthetic pathway to porp bilinogen. Four molecules of porphobilinogen are th employed in the formation of uroporphyrin, the a-N group at the right being split off. (From C. Rimingt "Porphyrins" in *Endeavour,* page 135, July, 1955. R produced by permission of the publishers.)

Of considerable interest is the recent emergen of porphobilinogen as the first pyrrol to be form along the anabolic pathway to heme. Hithe this was known only as the Ehrlich reacting co pound characterizing the urine in acute porphyr The isolation of porphobilinogen from such ca is an excellent example of the fashion in which relatively rare disease may provide the key to phenomenon of much more general significan

The first E. T. Bell Lecture of the Minnesota Pathological Society.

From the Department of Medicine, University of Minnesota Medical School and Hospital, Minneapolis. The studies in this laboratory have been supported in part under contracts with the Surgeon General's Office, U.S.A., and the Atomic Energy Commission. Presented in part at the meeting of the Minnesota Pathological Society, October 18, 1955.

This lecture will appear in three installments, of which this is the first.

e structure of porphobilinogen was established b Cookson and Rimington.[5] The studies of S min and co-workers[6] in this country, and of uberger and associates[7] in England, have clearly own that glycine and acetate are utilized in the osynthesis of porphobilinogen, with β-ketoadipic d δ-aminolevulinic acids as the intermediary mpounds. This relationship is well shown in gure 1, reproduced from a recent paper by imington.[8] The pathway from the porphobili-ogen to the protoporphyrin of heme is not so ear. It will suffice to note at present that the ncept of transition from porphobilinogen→uro-→copro-→protoporphyrin[9,10,11a] was not supported Dr. Schwartz' studies in this laboratory,[11b], hich suggested either that a primary change ight occur in some fraction of the porphobilinogen olecule, to explain the independent formation various porphyrins, or that the transition from ro- to copro- to protoporphyrin might occur only ith proporphyrins (porphyrinogens or reduced orphyrins).* Rimington[8] has recently mentioned e latter possibility.

Fig. 2. The anabolic and catabolic relationships of the porphyrins and bile pigments, in skeleton outline.

With this brief survey of the anabolic side it will be my purpose now to consider the problem of catabolism. In Figure 2 an introductury skeleton outline is shown contrasting the anabolic and catabolic aspects of hemoglobin metabolism, from the standpoint of the pyrrol compounds. In relation to this outline I shall strive to present what I consider to be the more important recent advances and relate them to the more essential information from the past.

Conversion of Hemoglobin to Bilirubin

Lest there might be some thought that this subject does not have its traditional place in pathology I will commence my story by reference to the article by Virchow in the first volume of his "Archives of Pathology," 1847,[12] in which he documented for the first time the classical observation that hemoglobin is converted to bilirubin, or as he called it, hematoidin, when blood is extravasated in tissue spaces. Many pathologists after Virchow have concerned themselves with the problems of bile pigment formation and pathogenesis of jaundice. Among these may be mentioned Ludwig Aschoff, John McNee, George Whipple, Peyton Rous, Frank Mann and Arnold Rich. Although in the ensuing three-quarters of a

---

*In a recent study with F. Bashour and S. Schwartz, be published in detail elsewhere, N_{15} labeled uro-orphyrinogen I was converted by dog liver homogenate, *vitro,* to coproporphyrin and protoporphyrin.

century after Virchow's observation there was continued argument as to whether his hematoidin was identical with bilirubin, the principal bile pigment, the crystallographic studies of Fischer and Reindel in 1923[13] left no doubt that crystalline bilirubin as obtained from cattle gallstones or bile was identical with that forming in the tissues from extravasated hemoglobin. As we shall see in the following, however, there is a question whether the process of isolation from gallstones or bile induces a molecular change from a differing compound to the well-defined crystalline bilirubin.

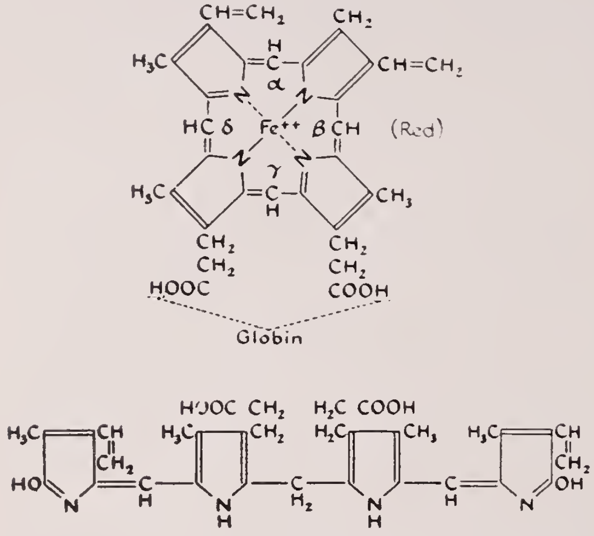

Fig. 3. Ferrous protoporphyrin globin (hemoglobin) and bilirubin.

The earlier history of the development of our knowledge of the origin of bilirubin and the pathogenesis of jaundice, these being clearly separate but closely related problems, is of much interest in its own right. I will do nothing more here than to sketch in a few of the important milestones, but to anyone who would interest himself in the earlier work on these topics, much of which has been too readily forgotten, I would strongly recommend Stadelmann's classic monograph on jaundice published in 1891.[14] Thanks to the generosity of Dr. Henry Ulrich, I am the proud possessor of a Stadelmann, and I have never failed to gain stimulus from reading the pages of his descriptions of the earlier work in this field.

According to Stadelmann, it was Tarchanoff who first proved beyond question that the bilirubin of the bile was derived from hemoglobin, indeed from the pigment fraction of the hemoglobin molecule. Tarchanoff[15] observed striking increa of bile pigment concentration in the bile of dc with bile fistulas, following the intravenous i jection of hemoglobin solutions or of bilirut itself, or following intravascular hemolysis induc by injection of distilled water. Minkowski a Naunyn[16] believed that hemoglobin was convert to bile pigment only in the liver. They work with geese in which the administration arseniuretted hydrogen ordinarily produc jaundice with ease. After removal of the liv jaundice failed to appear. Stern[17] had previou shown that jaundice failed to appear in doves w the common duct ligated, in which the liver h been excluded from the circulation by ligation all of its blood vessels. Stern had concluded fr these experiments "that since exclusion of t liver did not lead to the collection of bile pi ment in the tissues or secretion by the animal, t liver itself must be the site of formation of tl pigment." Minkowski and Naunyn reached similar conclusion with their geese and formulat the dogma "without the liver no jaundice."

With respect to Stern's conclusion, just r ferred to, Stadelmann made the following co servative but prophetic remark: "Can one rea draw a conclusion to such an extent? There w be many careful scholars who will prefer to su stitute" (in Stern's conclusion) "instead animal organism, organism of the bird, and w will raise the objection that the organism of t mammals, especially that of man, may behave in manner entirely different from that of doves This prophecy of Stadelmann was fulfilled McNee, then a young man working in Aschof laboratory in Freiberg, now Sir John McN emeritus professor of medicine in the Univers of Edinburgh. McNee pointed out that in gee the reticuloendothelial system is mainly conce trated in the liver and the spleen is almo rudimentary. Studying experimental hemoly jaundice, he found evidence that conversion hemoglobin to bile pigment was largely limited the liver in geese, but in mammals the spleen a bone marrow assumed much greater significance It remained for Mann and his co-workers to pe form the crucial experiment, namely, total hep tectomy in dogs.[19,20] I can well remember t clarity with which Dr. Mann presented the resu of these beautiful experiments to this society 1927. In brief, they revealed decisively an ext hepatic formation of bilirubin. Quantitative c mination of bilirubin concentrations in the blood and from the spleen and bone marrow showed importance of these tissues for the conversion hemoglobin to bile pigment. This work was idely confirmed, and the participation of extra-patic tissues in the formation of bilirubin was us clearly established.

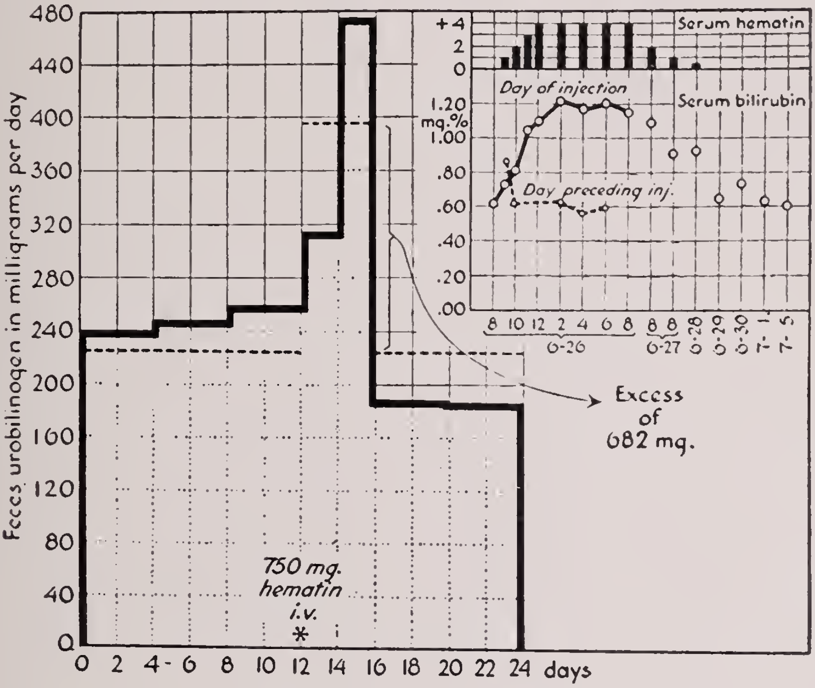

Fig. 4. Increase of serum bilirubin and fecal urobilinogen after intravenous injection of hematin in a normal adult human subject. (From I. J. Pass, S. Schwartz and C. J. Watson, *Journal of Clinical Investigation*, vol. 24, page 284, 1945. Reproduced by permission of the publishers.)

The formulas shown in Figure 3 epitomize the oblem of conversion of the heme in the hemo-obin molecule, to bile pigment. It should be oted that the hemoglobin molecule consists of ur heme nuclei, as shown, for each molecule of obin, the latter comprising about 96 per cent the weight of hemoglobin. We are only con-rned here with the fate of the heme or rosthetic fraction, though, as will be indicated, ere has been some belief that the protein is nportant in controlling the conversion of heme bilirubin.

The exact pathway of this conversion in the ody is still a matter of controversy. In the test ıbe hemoglobin is readily changed to hematin y relatively mild chemical treatment. This in-olves a change of the iron from ferrous to ferric, ith addition of an OH at the iron atom. Thus heme is a ferro-protoporphyrin, hematin a ferri-hydroxide protoporphyrin. The main excretory product of hemoglobin in the gastrointestinal tract is hematin and there is no conversion here to bile pigment. Possibly because of the ease with which hemoglobin is converted to hematin *in vitro,* earlier investigators, notably Brugsch[21] regarded hematin as the first intermediary in the pathway to bile pigment. Brugsch, in fact, was the first investigator to state that the intravenous administration of hematin in dogs with bile fistulas resulted in increased excretion of bilirubin in the bile. This was both confirmed and denied and there is a rather extensive literature on this controversy. The earlier work is well reviewed by Eppinger, 1920.[22] The most recent detailed discussion of the problem is to be found in Torben With's monograph, "The Biology of the Bile Pigments" (1954).[23]

Several observations led to a belief, for a time rather widely held, that hematin is a "blind alley" in hemoglobin metabolism, not converted to bile pigment. In particular this was based on the relatively rare occurrence of cases of "hematin icterus," in other words individuals whose blood serum contained only hematin and no increase in bilirubin.[24,25] Such instances were cited as evidence that hematin is not converted to bilirubin. Cases of this type are, or course, quite inconclusive as one must consider that the hematin may be steadily converted by the liver to bilirubin and that this is at once excreted. In a case of renal trauma and hemorrhage observed years ago in this clinic there was marked hematinemia without increase of the serum bilirubin, yet the feces urobilinogen was greatly increased.[26] While this did not prove that the hematin had been converted to bilirubin and thence to urobilinogen, such an explanation was quite compatible with the data. Subsequent studies with I. J. Pass and S. Schwartz,[27a] in which hematin was injected intravenously in normal individuals, gave clear evidence of a quantitative conversion to bile pigment. As seen in Figure 4, the amount of urobilinogen excreted in the feces agreed very well with expectation on the basis of the amount of hematin injected. Also, a significant rise in serum bilirubin was observed. In recent years this work has been fully confirmed by London[3b] using N_{15} tagged hematin; thus it is difficult to understand why the older studies of Gitter and Heilmeier[28] and of Duesberg[29] failed to reveal evidence of increased bilirubin or urobilinogen formation following injection of hematin. In any event the concept[24] that hematin is a "blind alley" in hemoglobin metabolism rather than an intermediary in the pathway to bilirubin gained wide acceptance because of these observations. For reasons that are not clear, Lemberg[31] was unwilling to accept the belief that hematin is converted to bile pigment, and has been a principal proponent of the view that the first intermediary, rather than hematin, is a "green" hemoglobin or biliverdin-iron globin compound. The first compound of this type to be described was by Fischer and Lindner, [30a] using yeast, but Warburg and Negelein[30b] provided a more exact chemical method by the coupled oxidation of a pyridine hemochromogen with hydrazine, providing what they called a "green hemin." Lemberg[32] later showed that this was a double salt of biliverdin dimethylesterhydrochloride and ferric chloride, differing significantly from Lemberg's "green hemoglobin," the latter being obtained by a coupled oxidation with ascorbic acid.

In essence, the green hemoglobin concept of bile pigment formation as championed by Lemberg, depends upon a primary opening of the protoporphyrin in hemoglobin by oxidative ı moval of the α-methene bridge. The resulting bi verdin is still bound to iron and globin. The fc mation of free bilirubin requires a splitting off iron and globin and the addition of two hydrog atoms to the biliverdin molecule. All of the changes are well within the realm of feasibili but their significance for the natural sequence events is not clear. There is controversy as to t occurrence of green hemoglobins in relation hemoglobin catabolism *in vivo*. Lemberg and c workers,[31,32] Kiese,[33] Engel[34] and other investig tors have reported that circulating red blood ce contain a small amount of a verdohemoglobi but the more recent studies of Kench and asso ates[35,36] cast serious doubt on this concept. Wh anaerobic conditions were employed the amou observed was extremely small and not larger th was obtained on crystallization of oxyhemoglobi Kench believed that these small amounts we probably formed during the isolation procedu and that the natural occurrence of verdohemogl bin in the red cells was doubtful.

While Lemberg and other proponents of the ve dohemoglobin concept regard a continued attac ment to globin as essential for biliverdin formatio Kench's studies clearly reveal that protein is u necessary and that hematin is readily converted bile pigment *in vitro,* under appropriate co ditions. It is true that in their experiments t yield was consistently better when the her (Fe^{++}) or hematin (Fe^{+++}) was combined wi protein, either globin or albumin, but it appear that the sole function of the protein in this rega was the protection of the biliverdin against fu ther oxidation after it was once formed. It w also clear in these experiments that the state the iron in the molecule was unimportant; just good conversion was observed with ferric iron hematin as with ferrous iron in hemoglobin heme. It may also be noted that London[3c] h demonstrated the *in vivo* conversion of N^{15} pr toporphyrin, as well as hematin, to bile pigme Previous studies in this laboratory,[27b] in bile rer fistula dogs, had failed to provide evidence such conversion but admittedly did not exclude Further work is necessary to elucidate the possit significance of protoporphyrin as an intermedia in bile pigment formation, under normal or a normal conditions.

Thus the exact pathway along which hem globin is converted to bile pigment in the mai nlian organism is not yet clear. Bingold and Sh[37] in their recent and latest review of this sject state that "in contrast to the still incompte knowledge of the biosynthesis of hemoglobin ıs possible today to provide an exact statement ato the biochemistry of hemoglobin catabolism." th all of the recent evidence in mind, especially t exact knowledge of the biosynthesis of protophyrin gained in the classic studies of Shemin l co-workers, and despite the optimism of Bind and Stich, one is inclined to the belief that t opposite is more nearly correct and that our sent knowledge of anabolism is more exact than at of catabolism. If, as according to Bingold d Stich, one accepts without question the Lemrg concept that the pathway *in vivo* is solely via green hemoglobin and that hematin is not an ermediary under any circumstances, one may quire a sense of security such as evidenced in eir statement, quoted above. Yet a careful exnination of the evidence makes one realize that is may be incorrect. The objection that hemah is never observed under normal circumstances, ut only in the presence of hemolysis and especially molysis associated with liver injury, in no way oves that hematin is not formed as a normal termediary and at once converted to bilirubin ther in the liver alone, as Aschoff[38] assumed, or ore widely, throughout the reticuloendothelial stem. It should be emphasized that Mann and o-workers[20b] regularly observed hematin at the utset of increased bilirubin formation in extraepatic sites and definitely regarded it as a normal ıtermediary between hemoglobin and bilirubin.

Earlier observations with I. J. Pass in this laboratory[26] indicated that epithelial specialization of ells is associated with a diminished production of he ferment necessary to bilirubin formation when emoglobin is extravasated. In such areas hematin vas often encountered without bilirubin whereas n spaces lined by mesenchymal cells bilirubin was often encountered without hematin, following extravasation of blood. These observations, however, permit two interpretations: one, that the epithelial cells do not have the ability of further conversion of hematin to bilirubin while the mesenchymal cells do; the other, that the epithelial cells convert hemoglobin to hematin, the mesenchymal cells hemoglobin to bilirubin, without hematin as an intermediary. The presence of hemoglobin, hematin and bilirubin in some fluids may perhaps be somewhat more indicative of the former possibility. It should be noted that the conversion of hematin to bilirubin may well proceed over a verdohematin analogous to the "green hemoglobin." It is quite possible that both pathways are included in the natural sequence of events, variations in emphasis depending on as yet unknown factors.

THE POSITION OF RADIOLOGY IN CARDIOVASCULAR DIAGNOSIS

(Continued from Page 280)

evidence of pulmonary sequestration by demonstrating the anomalous vascular supply to a segment of lung from the aorta directly. The method is useful as well in demonstrating arteriovenous communications in lung (Fig. 11) and to differentiate between gross cardiac dilatation and pericardial effusion. It has been used with profit to study pulmonary neoplasms.

The present position of radiology in cardiovascular diagnosis is one of major importance and each month that position is broadened and strengthened. In this field close co-operation with the specialties of cardiology and surgery is mandatory if the full benefits of angiography are to b realized. The haphazard employment of the ne and complex methods is not to be recommende and the most glittering radiographic images are c little value until they have been thoroughly an expertly analyzed. The required apparatus costly and highly specialized, but the great valu of the diagnostic results to be expected justifie the capital investment and the detachment of abl radiologists from other endeavors to devote them selves to this type of work and the further advanc of knowledge. The future of cardiovascular ra diology appears to be brilliant and assured.

ACTURES OF THE METACARPALS, METATARSALS ND PHALANGES

LESTER W. CARLANDER, M.D.
Minneapolis, Minnesota

Fractures of the metacarpals and phalanges of hand and metatarsals and phalanges of the t are very common problems with which we have to deal. Although these are not consid- d major fractures, the proper handling of them ds to a much happier patient and a quicker d more complete functional rehabilitation of e injured parts.

Fractures of the phalanges of the toes are com- on and of importance largely only because of eir nuisance quality. Most of these fractures can successfully treated by reassurance and by the e of proper foot wear. This involves the use of stiff sole (largely preventing motion in the toes curred in walking) and relief from pressure on p of the toe from the upper portion of the shoe ring the period which the toe may be swollen d painful. The use of traction can probably ell be reserved for displaced fractures extending to the articular surface at the metatarsal- alangeal articulation, particularly in the great e.

The metatarsal bones of the foot tend to splint ne another quite securely so that they do not sually become greatly displaced when fractured xcept with severe injuries. Treatment again can equently be accomplished by the use of a stiff led shoe with reinforced shank and proper longi- dinal and anterior arch supports. At times reater comfort can be obtained by the use of a ell applied short boot cast molded carefully be- eath the foot and application of a walking heel.

The frequently seen avulsion type fracture at he base of the fifth metatarsal may go on to brous union when displaced but is seldom symp- omatic. In children, confusion with the epiphy- is present at the base of the fifth metatarsal should e avoided. This will be bilateral and smooth. There is present in some feet a separate ossicle n this area, the os vesalianum, which again is sually bilateral and smooth.

The possible occurrence of "march" or "stress" fractures of the metatarsals is generally well known today. The rather spontaneous nature of this fracture or the appearance of callus or new bone involved in healing should not lead to consideration of biopsy nor amputation for bone tumor.

Avoidance of over-treatment of fractures of the foot may help to decrease the occasional prolonged rehabilitation seen with the development of painful osteoporosis.

In contradistinction to the toes, the function of the fingers is of extreme importance; and treatment of fractures of the phalanges in the hand is aimed toward the early re-establishment of this high degree of functional capacity. In general, splinting of fractures in the hand should be accomplished in functional position, this being the position of partial flexion. Tongue blade splinting is to be avoided. Splinting should be maintained only for that period necessary to allow sufficient healing to insure stability of the fractured fragments. Active motion may then be started to prevent undue stiffening of the metacarpal-phalangeal and interphalangeal articulations.

Fractures of the distal phalanx will usually merely require protection, particularly when the finger nail is intact. Fractures of the middle and proximal phalanx may require traction in order to prevent shortening and to maintain alignment. This traction may be either skeletal or occasionally skin traction. Traction should be applied over a curved splint, and the fact that each finger flexes in a different axis of rotation at the metacarpal-phalangeal articulation should always be remembered. Fractures extending into the joint at the base of the second and third phalanges are particularly troublesome and tend to give a broad and partially subluxated joint unless traction is maintained until good healing is present.

Fractures of the neck of the metacarpals are frequently seen particularly in the fifth and fourth metacarpals. Because of the nature of the fracturing force, the head is usually tipped forward into the palm and this palmar prominence of the head must be corrected in order to prevent a pressure point which may afterwards be bothersome in gripping. This angulation can usually be corrected by manipulative pressure using the flexed proximal phalanx to push against the palmar surface of the head of the metacarpal. In fractures of the shafts of the metacarpals, rotation deformities must again be considered and can be prevented by accomplishing reduction with the fingers flexed at the metacarpal-phalangeal joint and in apposition to one another.

Special attention should also again be called to the fracture at the base of the first metacarpal in the thumb which extends into the joint and allows a subluxation or dislocation of the main metacarpal fragment. This is called Bennett fracture. It is important that these fractures b maintained with complete abduction of the fir metacarpal, and as it is an unstable fracture, frequently slipping after reduction, traction on th abducted thumb is usually necessary. It is important that frequent radiographic checks be use in the first two weeks following reduction to se that position is maintained.

A word should be said about the use of Kirschner wires in the treatment of fractures of th metacarpals and phalanges. Fine Kirschner wire are frequently of great benefit in the treatmer of these fractures and may at times allow earl use of other portions of the hand.

By reviewing these injuries it is hoped that th reader may facilitate the care and rehabilitatio of these common fractures.

GALACTOSEMIA

The cause of an often fatal metabolic disease of children has been discovered by scientists of the Public Health Service's National Institute of Arthritis and Metabolic Diseases, according to Surgeon General Leonard A. Scheele.

Drs. Herman M. Kalckar, Elizabeth P. Anderson, and Kurt J. Isselbacher, in work conducted at the National Institutes of Health, Bethesda, Maryland, have unraveled much of the mystery surrounding the little understood children's disease, galactosemia, also known as galactose diabetes.

This disease ordinarily appears within a few days after birth. The infant suffering from galactosemia is unable to utilize or even tolerate milk in any form. Lactose, often called milk sugar, contains another sugar, galactose. This substance cannot be handled by the child's system if he has galactosemia.

The Institute scientists have discovered a hitherto unknown enzyme in normal red blood cells, which they call P-Gal transferase. This enzyme, they found, is necessary to complete conversion in the body of galactose into glucose, the common sugar of the blood.

Diagnosis of galactosemia is difficult because the symptoms are similar to those of other disorders. Diarrhea, lack of appetite, loss of weight, and jaundice appear in the earlier stages. In later stages, it leads to cirrhosis of the liver, mental retardation, blindness du to cataract, and death.

Early recognition of galactosemia is highly importan since the disease progresses rapidly, leaving serious irreversible changes. On the other hand, when diagnose in an early stage, treatment is simple. The affecte child, placed promptly on a milk-free diet, will grow and develop normally.

The discovery of the basic cause of the disease promise to provide a rather simple diagnostic test, making earlie life-saving treatment possible.

Scientists at the Institute became interested in th disease when research workers in Manchester, Englanc reported certain abnormalities in the red blood cells o infants with galactosemia. Their own work has reveale that the enzyme, P-Gal transferase, which they had foun in normal blood, was missing in the blood of childre with this disease, and that this inherited metabolic defec was the basis of the disorder. A report on their researc is published in a recent issue of the Proceedings c the National Academy of Sciences.

Knowledge of P-Gal transferase not only makes possible the development of a rather simple diagnostic tes for galactosemia, but it also points the way to exploration of the distinct possibility that impairments i galactose metabolism may be a factor in other disorde of unknown origin.

ACHROMYCIN*

Tetracycline *Lederle*

in the treatment of

respiratory infections

January and his associates[1] have written on the use of tetracycline (ACHROMYCIN) to treat 118 patients having various infections, most of them respiratory, including acute pharyngitis and tonsillitis, otitis media, sinusitis, acute and chronic bronchitis, asthmatic bronchitis, bronchiectasis, bronchial pneumonia, and lobar pneumonia. Response was judged good or satisfactory in more than 84% of the total cases.

Each month there are more and more reports like this in the literature, documenting the great worth and versatility of ACHROMYCIN. This antibiotic is unsurpassed in range of effectiveness. It provides rapid penetration, prompt control. Side effects, if any, are usually negligible.

No matter what your field or specialty, ACHROMYCIN can be of service to you. For your convenience and the patient's comfort, Lederle offers a *full* line of dosage forms, including

ACHROMYCIN SF

ACHROMYCIN with STRESS FORMULA VITAMINS. Attacks the infection—defends the patient—hastens normal recovery. For severe or prolonged illness. Stress formula as suggested by the National Research Council. Offered in Capsules of 250 mg. and in an Oral Suspension, 125 mg. per 5 cc. teaspoonful.

For more rapid and complete absorption. Offered only by Lederle!

dry-filled sealed capsules

What is a Municipal Bond?

A Municipal Bond is a contract between a city, town, village, school district, or any other municipality and the bondholder whereby the municipality acknowledges its indebtedness to the bondholder and also binds itself to pay the bondholder a certain sum of money on a definite date. Municipal Bonds are issued in denominations of one thousand dollars ($1000) each. Attached to each bond are interest coupons which the bondholder periodically detaches to receive his interest on the money he has loaned to the municipality.

AGNOSIS AND TREATMENT OF THROMBOANGIITIS OBLITERANS UERGER'S DISEASE)

NELSON W. BARKER, M.D.
Rochester, Minnesota

Thromboangiitis obliterans is a segmental in- nmatory obliterating disease of the arteries d veins of the extremities that tends to produce hemia of tissues and occasionally gangrene. It urs almost exclusively in young and middle- ed men. Typical lesions rarely occur in the cera but patients who have the disease also ve a somewhat increased tendency to undergo clusion of the coronary, cerebral and mesenteric eries later in life as the result of atherosclerosis, different pathologic process.

The exact cause of thromboangiitis obliterans is t known. However, available evidence indi- tes that the most important factor in almost persons in whom the disease develops is a culiar individual susceptibility of the vessels of e extremities to endothelial injury as the result absorption of some product in tobacco smoke.

Diagnosis

The ultimate criterion for the diagnosis of romboangiitis obliterans is a rather typical his- pathologic picture found in the affected vessels; ese characteristic changes include endothelial oliferation, occlusion of the lumen by a throm- is, extremely cellular organization of the throm- is and diffuse panangiitis without necrosis or struction of the medial coat. Not found are sub- dothelial atheromatous lesions containing fat d cholesterol or subendothelial or medial calci- ation. Primarily, the lesions affect small and edium-sized arteries, such as the posterior tibial, terior tibial and major digital arteries. In dition, veins accompanying these arteries and perficial veins of comparable size are frequently fected. The disease almost never begins in large arteries, such as the femoral and iliac, but occasionally it progresses into them from more distal branches.

The diagnosis of thromboangiitis obliterans almost always can be made clinically and without resorting to arterial biopsy. In making the diagnosis, it is important to remember that thromboangiitis obliterans is only one of several diseases that may produce ischemic manifestations in one or more extremities. It is most likely to be confused with arteriosclerosis obliterans. Sometimes, but less commonly, it is confused with peripheral arterial embolism, simple arterial thrombosis, scleroderma (acrosclerosis), Raynaud's disease, ergotism and arterial occlusions due to acute or chronic occupational trauma. In making the diagnosis of thromboangiitis obliterans, it is first necessary to establish the fact that occlusive arterial disease exists in one or more of the extremities.

Intermittent Claudication.—Intermittent claudication is an almost pathognomonic symptom of occlusive arterial disease. The currently accepted definition of intermittent claudication is a pain, ache, tightness, or sense of abnormal fatigue felt in the region of certain groups of muscles in the extremities that is never present during rest, develops only after a period of sustained exercise of the muscles and is relieved rather promptly by rest without change of position. Intermittent claudication is not a disease. It is a symptom and it indicates only the presence of some type of occlusive arterial disease. It may occur as the result of thromboangiitis obliterans, arteriosclerosis obliterans, arterial embolization or simple arterial thrombosis. In thromboangiitis obliterans, it may occur in the calf or in the arch of the foot, where it may be mistakenly attributed to mechanical derangements of the foot and arch. Intermittent claudication in the thigh or hip is rarely

---

From the Section of Medicine, Mayo Clinic and Mayo undation.

The Mayo Foundation, Rochester, Minnesota, is a rt of the Graduate School of the University of Minne- ta.

seen in thromboangiitis obliterans. Other types of pain that may occur in cases of more advanced chronic occlusive arterial disease in which the evidence of ischemia in the affected extremity is more obvious are rest or pretrophic pain in digits, pain associated with ulcers or gangrene and pain associated with ischemic neuropathy of major nerve trunks.

Arterial Pulsations.—The objective manifestations of chronic occlusive arterial disease are impairment or absence of pulsations in one or more of the major arteries of the extremities and, in advanced disease, abnormal pallor of one or more of the extremities on elevation, with delay in the return of color and in filling of superficial veins on dependency after elevation. Also, there may be abnormal and persistent coldness of one or more of the extremities or of one or more individual digits, persistent bluish or reddish discoloration of one or more digits, and gangrene or ulceration of one or more digits or parts of the foot.

In examination for impairment or absence of arterial pulsations, the brachial arteries, antecubital arteries, radial and ulnar arteries at the wrist, femoral arteries in Scarpa's triangle, popliteal arteries, posterior tibial arteries behind the internal malleoli and dorsalis pedis arteries should be palpated. However, impairment or absence of pulsations in one or both dorsalis pedis arteries is not necessarily significant of occlusive arterial disease, since these arteries are small or absent as the result of developmental anomaly in about 5 per cent of normal persons. Impairment or absence of pulsations in the posterior tibial arteries, however, is almost certainly indicative of chronic occlusive arterial disease. If the diagnosis of occlusive arterial disease has been established by objective examination, it is almost always possible to determine clinically the nature of the underlying arterial disease.

Other Diseases.—Raynaud's syndrome, or transient blanching of one or more of the digits on exposure to cold, may occur in thromboangiitis obliterans. The involvement of the digits is almost always asymmetric, whereas in true Raynaud's disease the involvement is usually symmetric. Arterial pulsations are not impaired or absent in true Raynaud's disease. The occurrence of sclerodactylia or scleroderma associated with Raynaud's syndrome indicates the presence of acral scleroderma (acrosclerosis), not throm angiitis obliterans.

Ergotism is comparatively rare in this coun except when the patient has taken or been gi medicine containing ergot or its derivatives. chemia of the extremities produced by ergotism almost always symmetric, whereas it is alm always asymmetric in the other chronic occlus arterial diseases. If arterial occlusion is due arterial embolism, there will almost always coexistent serious cardiac disease in the form recent myocardial infarction, auricular fibrillat or subacute bacterial endocarditis. Also, the or of the ischemic manifestations produced by em lization of the extremity almost always will h been marked by sudden arterial occlusion, wher sudden occlusion of large arteries is not common thromboangiitis obliterans. Simple or essential terial thrombosis is rare and usually is associa with polycythemia vera, severe infectious disease advanced malignant neoplasms. When none these are present, the diagnosis of simple arte thrombosis should be made with great cauti

Thromboangiitis Obliterans Versus Arterioscl rosis Obliterans.—The two commonest chronic clusive arterial diseases are thromboangiitis ob erans and arteriosclerosis obliterans. Some di culty may be encountered at times in differenti ing these two conditions, although the clini features now to be mentioned usually permit su distinction. Thromboangiitis obliterans almost ways produces its first clinical manifestations fore the age of forty years, whereas arterioscler obliterans usually appears after the age of fo There are a few exceptions to this rule, howev and patients who experience the first signs ischemia in an extremity between forty and fi years of age may have either disease. Throm angiitis obliterans is rare in women (1 per cer whereas about 15 to 20 per cent of cases of arte sclerosis obliterans occur in women. The prese of definite signs of ischemia in one or both ha associated with similar manifestations in the lo extremities is strong evidence in favor of throm angiitis obliterans, since such ischemic manife tions are almost unknown in the upper extremi of patients who have arteriosclerosis obliter A good history of thrombophlebitis or the act presence of the lesions of superficial thrombop bitis in small veins in association with occlus arterial disease occurs in about 40 per cent tients who have thromboangiitis obliterans but actically never is noted in arteriosclerosis literans.

The following are almost certain indications that e disease in question is arteriosclerosis obliterans her than thromboangiitis obliterans: (1) roent-ographically demonstrable calcification in the noral or iliac arteries; (2) the presence of dia-tes mellitus; (3) increased values for plasma olesterol and total lipides and (4) a systolic bruit ard over a femoral or iliac artery or over the dominal aorta. In the age group in which there most likely to be a question as to the differen-tion of thromboangiitis obliterans and arterio-erosis obliterans, absence of pulsations in pop-al and femoral arteries is much less common in romboangiitis obliterans except when the dis-se has been present for a considerable period, th gradual progression.

Treatment

Thromboangiitis obliterans is characterized by acerbations when new segments of arteries be-me occluded and remissions when there is slow velopment of collateral circulation around the cluded segments. The most important feature in e treatment is absolute insistence on abstinence om tobacco smoking. If the patient completely scontinues smoking, exacerbations of the disease e almost unknown. If the diagnosis is made rly in the course of the disease and if the patient ops smoking, the collateral circulation may de-lop to a point at which all symptoms and signs sappear other than absence of pulsations in some the arteries.

General Measures.—An important part of the anagement of patients who have thromboangiitis literans is instruction regarding care of the feet d hands and avoidance as far as possible of any inor or major injury to them, whether it be of echanical, chemical, or thermal origin. As in all nditions associated with chronic ischemia of an tremity, most instances of gangrene or ischemic ceration develop as the result of some minor d avodiable trauma, such as pressure on toe-ils from ill-fitting shoes, cuts or bruises, over-eatment of fungous infection or ill-advised treat-ent of corns, calluses or ingrown toenails. Major even minor surgical operations on the feet or es should never be undertaken in any patient ntil it has been determined that ischemia or evidence of occlusive arterial disease is absent; if signs of such disease are found, the surgical procedure should be deferred in almost all instances. The local application of strong chemicals should be avoided. Patients who have thromboangiitis obliterans should be warned to avoid exposure to cold, since even a minimal degree of such exposure sometimes may result in frostbite in an ischemic extremity. Also, they should be warned not to use any hot dry objects, such as hot-water bottles or electric pads, to warm an ischemic extremity. Unfortunately, many patients with thromboangiitis obliterans do not come under the care of a physician until the disease is well advanced. In these patients, considerable permanent damage already may have been done to the arterial system in one or more extremities, and the complications of ischemic ulceration or gangrene already may have occurred.

Patients who have ulcerative or gangrenous lesions should be treated in the hospital and should be kept off their feet in a warm room (75 to 80° F.). Only bland topical applications should be used on the lesions. The use of warm soaks with a solution of boric acid for 20 to 30 minutes two to four times a day, with application of simple dry dressings between soaks, constitutes a simple and safe local treatment. When gangrenous tissue has sloughed and residual ulcers are relatively clean, the use of powdered erythrocytes may expedite healing. In general, ulcers and gangrenous lesions should be undertreated rather than overtreated, since many local preparations and ointments that would be harmless when used in the absence of ischemia may aggravate and cause extension of lesions when ischemia does exist.

Local infection in the surrounding tissues almost always is associated with gangrenous and ulcerative lesions, and the organism usually responsible for this infection is Micrococcus pyogenes (Staphylococcus). Oral or parenteral antibiotic therapy may be of considerable value in eliminating these local infections, thus giving the tissues a better chance to heal. The most effective current antibiotic against the largest number of strains of M. pyogenes should be used unless it is possible to obtain the specific organism by culture and determine its sensitivity to various antibiotics.

Surgical Treatment.—Regional surgical sympathetic ganglionectomy is of value in many patients who have thromboangiitis obliterans and contraindications to this procedure rarely exist. The operation is not necessary when the disease is mild and early and is associated with minimal evidence of digital ischemia, whereas the procedure is futile in the presence of advanced ischemia, with extensive gangrene extending into the foot. When gangrene is confined to one or more digits, it is usually advisable to wait until evidence of progression has stopped before sympathetic ganglionectomy is done. Sympathectomy is indicated in most cases of moderate ischemia with or without minor ulcerative or gangrenous lesions. The use of various drugs for the production of vasodilatation is not often of value and is distinctly inferior to sympathetic ganglionectomy.

When mass gangrene of digits or portions of digits exists, surgical intervention should not be attempted until all evidence of local infection and inflammation around the line of demarcation has disappeared. Even then it is usually best to wait and allow the gangrenous tissue to slough spontaneously, but in some instances healing may be expedited by gentle débridement through the line of demarcation. Amputation of the entire toe through its base occasionally may be advisable; when this is undertaken, it should be always recognized that healing may be delayed and that more gangrene may develop at the site of amputation. Even in patients who have severe and persistent pain with gangrenous lesions, amputation of a leg should be delayed as long as possible. If smoking is stopped and unless the gangrene extends into the distal part of the foot, the lesions usually w heal ultimately. When gangrene extends into th foot, the ultimate survival of a useful foot unlikely and amputation through the midcalf almost always necessary.

Currently, surgical excision of occluded segmen of arteries with replacement by arterial homograf or prosthetic tubes is not practical in thromboa giitis obliterans because of the small size of th involved arteries and the multiplicity of the o cluded segments.

Summary

Thromboangiitis obliterans is a specific disea entity but it is only one of several occlusive arter diseases that involve extremities. The diagno almost always can be made clinically and t condition usually can be distinguished from oth chronic occlusive arterial diseases, including art riosclerosis obliterans, which is a somewhat mo common disorder.

The treatment of thromboangiitis oblitera consists of complete abstinence from smoking t bacco, careful protection of involved extremit against major and minor chemical, mechanic and thermal trauma, regional sympathetic gangli nectomy in most cases, conservative local trea ment and antibiotic therapy for ischemic ulcer tive and minor gangrenous lesions, and conserv tive amputation or débridement for mass gangre of digits.

CHRONIC PYURIA

(Continued from Page 284)

In some cases an infection will clear with a particular antibiotic, only to recur as soon as it is stopped. Here one should reinstitute the original treatment until the urine clears, then gradually reduce the dose in an effort to ascertain the minimum which will keep the urine clear without harming the patient. One such patient of mine has taken one 250 milligram capsule of aureomycin daily since it first became available, without any ill effects; if he stops it, his urine clouds up at once. Since he has large bilateral hydronephroses which preceded a successful transurethral resection, this suggests the potential usefulness of this regimen.

A method used at the Mayo Clinic in similar circumstances involves giving the agent which h been found to be capable of clearing the urine one week of each month.

Careful application of the principles outlined i this presentation will control the majority of u nary infections one should not hesitate to rep any indicated part of the investigation to make su that nothing has been overlooked. A few w persist regardless of the methods used to com them; in the present state of our knowledge must await the development of new agents. F tunately, some of these patients will survive, parently unharmed, for many years especially f the kidneys do not become involved.

ublic Health

IAGNOSTIC STANDARDS AND LASSIFICATION OF TUBERCULOSIS

E. A. MEYERDING, M.D.
Saint Paul, Minnesota

The tenth edition of *Diagnostic Standards and assification of Tuberculosis,* published by the tional Tuberculosis association, has recently en distributed to Minnesota physicians, medical udents and public health nurses by the Minne- ta Tuberculosis and Health Association.

Designed to bring the reader up to date in sev- al fields, the new edition is the result of almost o years of work by an American Trudeau So- ety committee headed by William Spencer hwartz of the Veterans Administration Hospital, teen, North Carolina.

In a revision of the clinical classification of pul- onary tuberculosis, the term "arrested" has been opped and the nomenclature confined to "inac- ve," "active," and "activity undetermined." A ction on the diagnosis of nonpulmonary tuber- ulosis and a section on fungi pathogenic for man ave been added. The latter addition was made ecause some fungi "produce diseases that mimic e clinical and pathological signs of tuberculosis such an extent that the mycoses must be con- dered in making a differential diagnosis."

The section on the tuberculin test has been nlarged to an entire chapter in recognition of its owing importance. Abstracts from this chapter llow:

> "There has been much discussion of the value of the berculin reaction as a case-finding tool. As a screen- g test it identifies on the one hand persons who do ot need further testing or examination for the presence tuberculosis, and on the other those who do need rther study. Its value as a screening test is generally w in population groups where tuberculous infection is widely disseminated that the majority of persons act, and correspondingly high in population groups here dissemination is restricted and few react to the st. The tuberculin test has special value when em- loyed periodically in groups with unusual exposure to e disease, such as nurses, doctors, and students in hospitals or other places where cases of tuberculosis may be concentrated."
>
> ". . . Of the tuberculin tests, the intracutaneous method is the most sensitive. It permits the administration of accurately graduated amounts, thus making it possible to detect cases with a low threshold of sensitivity to tuberculin. The general use of the Pirquet and the patch tests is not recommended since they are not as reliable as the Mantoux, particularly in adults."

Changes in the treatment of tuberculosis are reflected in the insertion of a chapter on bacteriology as it relates to chemotherapy in which special attention is paid to the principles involved in tests to determine the drug-susceptibility of tubercle bacilli. Several paragraphs are devoted also to a description of methods to be employed in order to study bacteria in lesions removed by surgery.

The chapter on screening classification for mass chest x-ray surveys deals with two kinds of mass surveys which have been "highly successful"—community-wide and special group surveys. Emphasis is placed on the importance of x-raying all hospital admissions and outpatients. "The effort to promote and maintain the hospital's interest in this program is well repaid," the book states," as experience indicates a three to four times greater incidence of tuberculosis than is found by chest roentgenologic surveys of the general population. Also, attention may be drawn to other pulmonary and cardiac abnormalities hitherto unrecognized."

Ever since 1917, when the first formal edition appeared, *Diagnostic Standards* has made possible a uniform interpretation of diagnostic findings in tuberculosis and served as a guide for terms used to designate the disease state. Today, *Diagnostic Standards* is known the world over. It is the standard reference book for medical students in this country and is widely quoted in medical literature in this country and abroad.

CHANGING CONCEPTS IN PSYCHOSOMATIC REACTIONS

The fact that psychophysiological mechanisms play a significant role in the development of disease is almost universally accepted by both medical scientists and clinicians. However, when it comes to formulating the nature and mechanics of the psychophysiological processes, there has been much less general agreement. The medical literature reflects definite changes in psychosomatic theory. Earlier studies associated typical overt personality descriptions with specific psychosomatic disorders as, for example, the driving, ambitious, successful person with peptic ulcer. Following this, there was an attempt to attribute the cause of a particular disorder to psychological factors which were both specific and symbolic. Peptic ulcer was said to result from a conflict between the wish to be cared for and a striving for independence. More recently, the trend has been to consider that many different psychological factors may produce a given disorder with the nature of the response depending upon constitutional factors and acquired vulnerability of the organ involved. Thus, peptic ulcer may be produced by conflict over dependency needs, conflict about expressing hostile or aggressive impulses, conflict regarding sexual (masculine-feminine) drives, or combinations of these conflicts within a given individual.

This concept of multicausality has become increasingly popular under the aegis of controlled laboratory and clinical research. One reads with increasing frequency statements to the effect that investigators are less impressed with differences in the personality structures of patients with different psychosomatic reactions than with the similarities. Whether continued research will support the multicausality concept of psychosomatic reactions remains for the future. What does seem important at this point is that the problem is continually being more objectively evaluated by research methods rather than by setting about to "prove" by *post facto* means a particular pet theory as had been done earlier.

Clarence J. Rowe, M.D.

AGAMMAGLOBULINEMIA

Agammaglobulinemia, a newly recognized m
abolic disorder of the reticulum mesenchyme, w
first described by Bruton in 1952. His initial o
servation of electrophoretically absent gamn
globulin in a pediatric patient suffering from r
peated bacterial infections sounded the keynote
this disease. Subsequently, as many more repor
began to appear in the literature and clinical e
periences accumulated, two distinct forms we
delineated, the congenital and the acquired typ
The congenital type occurs only in male childr
and is transmitted as a Mendelian sex-linked rece
sive trait. The acquired type is found in both ma
and female adults, with no particular selective d
ferentiation with regard to age, and a history
previous good health is usually obtained.

The concept of immunologic paralysis in th
disease became apparent quite early to students
this disorder, in that in either the congenital or tl
acquired type, recurrent bacterial infections appe
to be a common denominator. Other findin
common to both include absence of iso-hema
glutinins, failure of plasma cell formation, a
sence of antibodies from the blood and tissues, a
failure of immunologic response to antigenic sti
ulation. A classical demonstration of the abo
was the successful transplant of a homograft
an agammaglobulinemic patient by Good a
Varco.

An important relationship stressed by Good h
been the absence of gamma globulin and co
comitant failure of plasma cell production. T
would implicate the plasma cell as being respo
sible for the formation of antibody and proba
gamma globulin as well. In one of Good's patie
who had resection of a lobe for bronchiecta
microscopic sections failed to reveal the prese
of any plasma cells. Although, characteristica
this cell type is very commonly encountered
pathologists in chronically diseased tissues,
plasma cells were found on microscopic exami
tion in this patient. Further antigenic stimulati
of lymph nodes, which in the normal person r
ularly results in medullary plasma cytosis, fails

duce plasma cell formation in nodes of the ammaglobulinemic patient.

Hypogammaglobulinemia and agammaglobu- nemia may be encountered as either a manifesta- on of a physiologic phenomenon or the result of disease state apart from agammaglobulinemia. he former is encountered as a delayed assump- on of gamma globulin production on the part of e infant, during which time progressive decrease the serum level of the passively transferred aternal gamma globulin is occurring. During is time, susceptibility to bacterial infections may increased just as in congenital agammaglobu- nemia.

The occurrence of hypogammaglobulinemia ay be noted as part of the nephrotic syndrome in ildren. Here, however, hypo albuminemia dif- rentiates between the electrophoretic patterns in e two conditions.

Paradoxically, agammaglobulinemic patients em to handle most virus infections well. How- er, virus hepatitis resulting in liver destruction ad death has occurred in these patients.

Prophylactic treatment with gamma globulin as proved successful in children. Although there some question of its efficacy in adults, at present seems the treatment of choice for agammaglobu- nemia. The recommended dosage is 0.6 cc. of andard gamma globulin preparation per Kg body eight given at four-week intervals. It may be hat the prophylactic antibiotic treatment will of- er even better protection of adults with agamma- lobulinemia or that a combination of the two ap- roaches will be the most effective means of pre- enting disease in these patients.

STATE PLANNING FOR PHYSICIANS

It has been said that it is just as important for very doctor to have a well-conceived, current state plan for the benefit of his family as it is for very family to have the services of a doctor. This true. No course of treatment is possible if death liminates the opportunity to plan one's affairs.

In our work as executor of wills, as trustee of oth living trusts and trusts under wills, and as in- estment agent, we have seen the estate plans of any doctors, which have been prepared by their ttorneys. It has been our duty, acting either alone or in conjunction with a friend or a member of the family, to carry out the terms of the plan as expressed in the will or trust agreement. From this experience, we can make certain generalizations. Often the estate of the doctor consists of a fine home, a comparatively large life insurance program, securities, and the value of his practice. The latter may be a sole interest or a partnership interest. In rural areas, the doctor may have investments in farm lands.

The value of all of the above property is includable in the doctor's taxable estate. In most cases, this value exceeds $60,000, the amount of the federal estate tax exemption. Thus, the doctor needs the benefit of careful estate planning to make sure his estate qualifies for the "marital deduction." This is a provision which enables an estate owner to pass to his surviving spouse, either outright or in trust, one-half of his estate free of federal estate taxes. It is also very important that the "second set" of taxes be saved for the benefit of his children.

The doctor should be sure that the management of his assets will be in experienced and competent hands after his death to assure the security of his family and to relieve his wife of these unfamiliar burdens. If the doctor is relatively young, he should be concerned about not only the care and support of his wife in the event of his death, but also the education and maintenance of the children if both he and his wife die during the minority of the children.

If he is in a partnership, it is probably advisable that he have a partnership agreement, and in many cases a buy-and-sell arrangement with the other partner or partners, possibly funded by life insurance.

If the doctor is in a high income tax bracket and has any sizable amount of income-producing assets, he may find it advisable to create short-term trusts, the income from which, during the ten-year period, could be taxed either to the trustee or to his children.

The doctor may find it advisable to make gifts and use part or all of his gift tax exemptions, both state and federal. Such gifts would remove part of his estate from the top death tax brackets.

Since the doctor is a busy man engaged in the most rewarding of all professions, from the standpoint of service rendered to humanity, he very seldom can give adequate time to his own financial affairs. He should investigate the services offered in an investment management agency account, in which investment recommendations are made to him, his entire portfolio is constantly reviewed, and all detailed work is done for him.

Because estate planning is the best use and arrangement of a person's property to carry out his objectives, every doctor needs estate planning to a greater or lesser degree as every layman may need medical assistance in varying degrees. Where does the doctor get his estate planning help? The key man is the attorney. All legal instruments, such as a will or a trust agreement, and the solution of all legal questions are matters for the doctor's own attorney.

Any trust company will be happy to share with the doctor the experience it has gained in the practical administration of many estates and trusts.

Harry L. Holtz
First Trust Company of Saint Paul

PAINT—ITS USE AND VALUE

Although paint and protective coatings have many uses and affect many phases of everyone's life, we might consider in a very limited manner its value as protection of property—home, building and the like—and— its value as beauty and decoration.

As a protective coating, paint is used to guard and protect property against the weather and ravages of rust and rot. Of course, thinking of exterior painting, the value of the home is also enhanced by beautifying its appearance. Exterior paint makes houses more pleasing to live in and gives people pride in their homes and neighborhood.

In studying the painting of the exterior and interior of a home, we run into the same problems that affect every type of structure, be it a store building, office, school, or institution. The exterior of a house may be constructed of a combination of materials such as wood, concrete, stone, brick, shingles (wood, asphalt, cement-asbestos), sash and doors of wood, aluminum and steel, all of which require different paint materials for the different assignments for protective coating and color. Whether you do the painting yourself as a hobby or out of necessity, or hire someone to do it for you, you should seek the advice and information regarding preparation, types of materials and methods of application from some reliable paint salesman or paint store or the services of a reputable painting contractor adequately covered with insurance. Too often paint failures result fro improper preparation, application and materi that cause no end of trouble and expense lat on. The very best paints placed in the hands unskilled or careless individuals will usually applied improperly and result in unsatisfacto service and appearance. A few basic principles remember when painting are: (1) be sure t surface you are painting is dry, (2) that moistu is not trapped behind the paint, (3) that paint not applied in too heavy a coat and the old co ings that are too thick, scaling and cracking ha been removed before applying another coat, (that each coat of paint is thoroughly dry befo another is applied, (5) and, last but not least, th the proper type of material for the surface to painted is selected and that quality material used.

The interior of a home or building, of cour is not painted with any thought of protecti against weather damage but as protection agai the hard knocks given by human beings as w as for beauty, cleanliness, light reflection and t like. Floors, more than any other surface, rea need protection against the hammering of hee unless they are completely carpeted. If the flo is of new wood it should be machine sanded fir followed with at least two applications of flo sealer and waxed; or, varnished two or thr coats. The only maintenance necessary from t point on would be washing and, on occasio rewaxing. Floors with a satin or dull finish ha more beauty than with a glossy finish. Ceilin and walls, whether plaster or drywall constructi (sheetrock), should be painted or papered with thought of applying a lovely color that wou give a smooth and eye-pleasing quality. If pai ed, a flat paint of the "alkyd" type should used with careful consideration in choosing col that will give pleasing, inviting and harmonio surroundings. Should you wish to paper wa that have been previously painted, all that necessary is to wash and prepare them first befo papering. However, if the walls are paper and you should wish to paint them, it is a go practice to remove the paper first, then wash th oughly and prepare before painting. In painti woodwork that has been previously painted, is always good practice to wash thoroughly fir prepare (sandpapering, puttying up holes a cracks and touching up bare and worn spots then apply an enamel as a last coat (gloss, sen oss, eggshell, satin or dull finish). In most cases, finish such as a low semi-gloss or eggshell gives e most pleasing finish. For many years now, has been a desire of people to paint the woodork the same color as the walls or to match e background of the wallpaper. In areas such kitchens and bathrooms that are to have the ilings and walls painted, it is best to use the ne type of material (enamel) that has been ntioned above for woodwork.

In closing, it may be said that a painted surface ceiling, wall or woodwork—may last a long ne if properly cared for and washed properly. important step in washing is not to use the ap solution too strong and to rinse after washg with a soap solution. To repeat, paint is of emendous value from the standpoint of protecon, beauty, cleanliness, light reflection, safety d health.

HE HISTORY OF GLASS CONTAINERS

Glass, like sunshine, is such a basic part of eryday life that we never give it a thought. But ithout glass—as without sunshine—it would be dark and barren world. There would be no indow panes or electric light bulbs, no microopes or thermometers, no mirrors or eyeglasses. cameras, television or hundreds of other things hich contribute either to the preservation or enyment of life.

And without glass, there would, of course, be no ass jars or bottles. Made by the billion in merica today, glass containers bring us an almost dless list of foods, beverages, medicines, toiletries d household products, which we could not do ithout. Produced in every shape and color, and nging in size from the tiniest medicine bottle to ant demijohns holding many gallons, these durle, transparent and attractive bottles and jars ave a rich and romantic history stretching back r thousands of years.

Just when and where the first "man-made" glass as produced has never been determined. One ncient legend credits a group of Phoenician ilors with making the world's first glass. The ory goes that the Phoenicians beached their boat n the sandy shores of a tidal river. Finding no cks on which to rest their cooking pots, they used lumps of natron—a crude soda ash cleansing agent—from the ship's cargo. Fanned by sea breezes, their camp fire blazed hot. When it died the sailors found in the ashes a shiny substance which became hard when it cooled. Since two of the basic ingredients of glass are sand and soda ash, this may have been how one of man's greatest gifts—glass—was accidentally discovered. Actually, nobody knows.

It is known, however, that many thousand years before the birth of Christ, Egyptians, and possibly some of their neighbors, were producing glass which they used to glaze or coat small stones to make beads. The world's first glass containers were made in Egypt some four thousand years ago by an extremely slow and laborious process. Using metal rods, Egyptian glassmakers pulled glass threads from a cauldron of molten glass and painstakingly wound the strands around a mold formed of sand. After the glass had hardened, the sand was scraped away to leave a hollow container.

Ancient craftsmen continued to make glass jars and bottles in this slow and tedious way for hundreds of years. Finally, however, the blowpipe—a long hollow metal tube with a bell-shaped end, was invented about 300 B.C. Blowers dipped the end of the blowpipe into a molten batch, gathered up a small gob of glowing glass, and formed it into rough shape on a marble slab. Then, blowpipe to lips, the glassmaker raised the pipe about his head, twirling the glass through the air in circles to create the shape he had in mind by centrifugal force. This free-blown method obviously required great skill—as well as time and lung power! Molds were the next milestone in the long and slow evolution of glass containers. This combination of blowpipe and mold made it possible to produce more uniform and more decorative bottles, jars, flasks and other hollow ware in a fraction of the former time.

ALCOHOL AND DRIVING

There are more than sixty pathological conditions which have some or all the symptoms of intoxication. Some time ago a police officer reported that he had followed a car for several blocks because the car was weaving. He found that the driver's speech was incoherent, and that he stag-

---

First in a series of editorials on the subject of glass nd glass containers.

Third in a series of editorials on alcoholism.

gered. The driver insisted that he had *not* been drinking, and that if he could have a candy bar, he would be all right. He was given candy and within a few minutes he was perfectly normal. Here was a diabetic person who had had an overdose of insulin. Thus it is possible that an innocent person may be accused.

To provide definite evidence, chemical tests should be given.

The standards for indicating degrees of intoxication are usually expressed in terms of percentage of alcohol in the blood.

When alcohol is taken, it passes unchanged into the blood stream which carries it to all parts of the body in direct proportion to the water content of the tissue or organ. It is the effect upon the brain that produces the symptoms of intoxication.

Blood alcohol level:

.02%-.20%	Stage of euphoria.
.12%-.28%	Stage of incoordination. There is no doubt that above .15% the person is under the influence of an intoxicant.
.24%-.40%	Stage of confusion. The man is drunk.
.32%-.50%	Stage of complete anesthesia. Sometimes the individual will "pass out."
.50% or over	Stage of grave danger. The individual is in danger of death.

The American Medical Association has agreed upon standard figures as a guide to legal procedure. In some places these have been written into law. If a person has .15 per cent or more alcohol in the blood, he is unquestionably under the influence of liquor.

Alcoholism, Inc. of Minnesota.

THE TREATMENT OF TUBERCULOSIS TODAY

Popular belief to the contrary, tuberculosis is not yet headed for extinction. In fact, after years of watching the steady decline in deaths from this cause, we now reach the paradoxical position of treating about the same number of patients that we were treating several decades ago. The discrepancy is more apparent than real, of course, the high prevailing incidence merely reflecting the survival nowadays of chronic cases whose disease would have proved fatal in the pre-streptomycin era. Then, too, there is the added factor of vastly improved case finding. The important thing is that tuberculosis still constitutes a problem of n small magnitude.

Even so, there can be no questioning the clai that there has occurred more progress in the trea ment of tuberculosis since 1947, the year th streptomycin became generally available, than i all previous years put together. There remai many unsolved problems, it is true, but much the early controversy about chemotherapy has bee resolved and there now exists some unanimity opinion as to how the average fresh case of tube culosis should be managed.

In the initial studies of streptomycin, it soo became apparent that the tubercle bacillus rath promptly grew resistant to streptomycin giv alone. Quite opportunely, it was discovered th the combination of streptomycin and par aminosalicylic acid (PAS) significantly delayed t development of bacterial resistance. Still later, was found that twice weekly streptomycin a ministration was no less effective than a dai schedule, with the added advantage of furth prolonging bacterial sensitivity to streptomyci though lessening the hazard of cumulative toxicit

Isoniazid, since its availability in 1952, h earned a place alongside streptomycin and PA As with streptomycin, bacterial resistance i variably attends the administration of isoniazi alone, but is considerably delayed by giving stre tomycin or PAS concomitantly. Current belief that all three possible combinations of drug namely, streptomycin and PAS, isoniazid and PA and streptomycin and isoniazid are equally effe tive. The use of all three drugs at once seems t provide no additional benefit and is best avoide Because of the possibility that isoniazid-pyrazin mide combination may prove to be equally if n more effective, it might be wise in the averag virgin case to defer the use of isoniazid, in th event a second course of therapy should ever necessary. This would not apply in cases miliary or meningeal tuberculosis, where isoniazi is particularly efficacious.

The accepted dosages are: streptomycin, gram intramuscularly twice weekly; PAS, 12 gra orally daily in three divided doses; isoniazid, 3 mg. orally daily in three divided doses. As y neither pyrazinamide nor cycloserine can be a vocated because of the unresolved question toxicity.

Ideally, treatment should be instituted early, few weeks sometimes making a big difference b

use of the necrotizing nature of the infection.
eatment should be continuous, for interrupted
erapy tends to increase bacterial resistance.
eatment must be prolonged or reactivation may
sue. For practical purposes, it can be said that
emotherapy should be continued for at least six
nths after all lesions can be classed inactive,
at is, six months after serial x-rays indicate
bility, planigrams show closure of all cavities
d the sputum is consistently negative for
bercle bacilli.

Other measures deserve comment. Bed rest,
ce the keystone of antituberculous therapy,
ould be used with prudence. Certainly, in the
ute phase of the disease complete rest is in-
spensable, leading to a reduction in fever, cough
d expectoration. Conversely, once symptoms
bside, an overly rigid attitude toward bed rest
ay promote discontent without contributing sig-
ficantly to treatment. At the opposite extreme,
e so-called ambulatory treatment of the tuber-
lous patient, while reducing the disability period
d hospital expense, may also reduce the chance
r cure.

Collapse measures, such as pneumothorax, pneu-
operitoneum and phrenic nerve crush, seem to
ve a steadily diminishing value, being at this
ne of more historical than practical importance.
oracoplasty is still a good operation with a high
te of cavity closure in selected cases. In gen-
al, however, outside of chemotherapy excisional
rgery stands out as perhaps the most important
cillary measure in the treatment of the disease.
resecting diseased tissue, especially cavitary dis-
se, permanent arrest of the infection may be as-
red. In essence, surgery is utilized for any
ngerous residua of chemotherapy.

As emphasized elsewhere, "the secret to the suc-
ssful management of the patient with pulmonary
berculosis lies not in any one drug, nor in any
e surgical feat, nor in any one therapeutic
ctum, but in the carefully planned and integrat-
use of all these many measures under the joint
pervision of the internist, bacteriologist and sur-
on working with the closest possible co-ordina-
on."†

J. Winthrop Peabody, Sr., M.D.

READER INTEREST POLL

At this year's Minnesota State Medical Association's meeting in Rochester, Minnesota Medicine will have a booth devoted to a *Reader Interest Poll.* The purpose of the poll is to learn how this journal can improve its service to its readers. Minnesota Medicine is your journal, so you have a strong motive to seek out this booth and let us have five minutes of your time to record your opinions about the journal.

The poll will be conducted by professional pollsters from the Department of Journalism of the University of Minnesota and will cost you money . . . even if indirectly. That gives you an additional motive to visit the polling booth; i.e., to make sure that you are getting your money's worth.

Give us the benefit of your opinions at the Rochester meeting.

The importance of environmental factors upon morbidity and mortality of tuberculosis has long been recognized. In a disease where the invasive powers of the agent are in such delicate balance with resistance of the host, factors which substantially augment the virulence of the causative organisms or depress the resistance of the host logically will determine the trends of the disease.—Alton S. Pope, M.D., and John E. Gordon, M.D., *American Journal of Medical Sciences,* September, 1955.

President's Letter

A TRIBUTE TO ORGANIZED MEDICINE

A few days hence we shall be gathering at Rochester for the 103rd Annual Meeting of the Minnesota State Medical Association.

To most of us this is primarily a scientific meeting, providing an opportunity to bring ourselves up to date on medical knowledge and equipment, but the meeting also provides some 100 commercial exhibits where you can see and study the latest in equipment, drugs and techniques. For your relaxation, there are special society luncheons and dinners and the usual assortment of sports events on the Sunday preceding the meeting.

This is what the annual meeting means to most of us. We have splendid meetings, and Minnesota can justly be proud of their caliber. But I wonder whether we ever give much thought to another side of our annual meeting.

Have we ever realized and appreciated the months of organization and preparation that the committee on local arrangements of the host city must engage in so that everything runs smoothly? Do we ever think of the effort put forth by Executive Secretary Rosell and his staff in providing the exhibits which are so vital to the financial success or failure of such a meeting?

Do we realize how much easier it makes the job of selling exhibition space if we stop to register with the exhibitors?

Do you realize that the Council and officers of the Association arrive on the scene the Saturday preceding the meeting; that from then until the close of the session they are in almost continuous session, usually starting with a 7 a.m. breakfast?

Do you appreciate the fact that the reference committees meet at 10 a.m. on the Sunday preceding the meeting?

To the House of Delegates, the annual meeting means two long sessions on Sunday preceding the meeting and another one on Monday, and, believe me, those chairs get harder and harder!

Do you set aside time at your succeeding component society meeting for your delegate to make a report so that you may be kept informed on current problems, or do you make him fight for a few minutes' time? I was a delegate for fifteen years from my component society and I am embarrassed to state how few times I was asked or given the opportunity to make a report.

So much for the annual meeting. There is much more to organized medicine in Minnesota and every other state. Do you know that there are twenty-three state scientific committees with a total of 239 devoted men serving on them, giving freely of their time and knowledge that the people of Minnesota might have better health?

In addition, there are approximately twenty-five non-scientific committees with a total of 190 members. These committees are concerned with editing and publishing our journal, with medical economics, medical relations, malpractice insurance, physicians' assistance, and numerous other phases of organized medicine. Mention must also be made of the fine group of men who over the years have given so generously of their time and talents in representing us as delegates to the two annual meetings of the American Medical Association and meetings of national committees on which they serve.

This letter is not meant to be critical, but rather as a tribute and expression of appreciation of the time and talents all of these members have so graciously and devotedly given to the cause of organized medicine. Their only reward is the satisfaction of a most worthy job well done.

R. H. Wilson

President, Minnesota State Medical Association

Medical Economics

Edited by the
Committee on Medical Economics,
Minnesota State Medical Association
George Earl, M.D., Chairman

DMINISTRATION OPPOSES DISABILITY AYMENTS UNDER SOCIAL SECURITY

The Eisenhower administration is firmly op- sed to two major provisions of the House-ap- oved social security amendments (H. R. 7225, mmarized in the January, 1956, section on ledical Economics"). These provisions are the vering of the retirement age for women, from ty-five to sixty-two and cash payments to dis- led workers at age fifty. The position was set rth March 22 by HEW Secretary Folsom, the 1st and final witness to appear before the Senate nance Committee since last January.

Folsom said that the medical testimony pre- nted on the difficult problem of determining gibility for disability payments, in his judgment, s very convincing.

He also stated:

> "The nation has already made significant progress in cent years in helping the disabled. About 244,000 edy disabled persons are now receiving payments of 65 million annually. Under the present system, cash yments are made only upon death or retirement. These nditions are easy to determine.
>
> "Under the disability proposal, however, the primary ndition for payment would be 'inability to engage in y substantial gainful activity, or mental impairment ich can be expected to result in death or to be of ng continued and indefinite duration.' These condi- ns are much more difficult to determine.
>
> ". . . Numerous medical witnesses have testified to is committee as to the great problems which they fore- e in evaluating physical and mental conditions for rposes of disability determinations. I believe the stimony of so many medical experts as to the problems volved in determining disability must be given con- lerable weight."

ifficulties in Controlling Cost

Folsom went on to discuss the uncertainties of e cost of such a program. He pointed out that e "cost estimates for disability are subject to a r wider range of variation than for other types benefits."

"It would also be possible," he added, "that e age limit of 50 could be lowered and that sh disability benefits at any age would cost so- al security taxpayers almost $1½ billion a year 1980."

Relationship to Vocational Rehabilitation

In discussing the relationship of cash disability benefits to vocational rehabilitation, Folsom said he believed that the latter was the most constructive approach to disability. He added:

> "Witnesses have testified that cash benefits may reduce the incentive of some disabled persons toward rehabilitation—particularly if the benefits, when combined with other resources, adequately meet essential needs.
>
> "Our own experience with the rehabilitation process," he said, "indicates that the drive and willpower of the individual is the most important single factor in determining his chances of successful rehabilitation. The committee is faced with a proposal for legislation in a delicate area of human motivation. It is impossible to proceed with the same degree of assurance that has accompanied other steps in the expansion of the social security system."

Summarizing his objections Folsom said:

> "There is a great divergence of opinion on the difficulties of administering a cash disability program, our ability to control the costs and the effects on vocational rehabilitation. On the other hand, we are making significant progress in helping disabled people—through assistance payments to the needy, the rehabilitation program and the disability freeze. We need more time to develop these programs fully and to evaluate their results."

Opposition to Lowering Retirement Age for Women

Referring to the section in the bill lowering the retirement age for women, Mr. Folsom noted that this would cost about $400 million the first full year and more than $1 billion annually by 1970. The proposal has been considered carefully several times in the past twenty years, but "Congress has always concluded that any overall values of a lower retirement age were outweighed by the heavy cost. And there has been a serious question as to the logic of a discrimination in retirement age between women and men."

Writing Your Congressman

Physicians are urged to continue writing thoughtful letters to their congressmen on their objections to H.R. 7225, although it is believed the Senate Finance Committee will go slow on Social Security revisions and that floor action will not come until midsummer.

On this and other issues, doctors have had a number of reasons in recent years to take special interest in their congressmen. The health question has certainly made taxes and defense, for example, items of conversation, and congressional study of almost secondary political importance. Physicians throughout the nation should express themselves from time to time on matters that concern them and their patients. As a practitioner, he has a right, too, to demand things that best enable him to practice the type of medicine for which he has trained and devoted himself.

The Hoover Report Division of the Taxpayers' Federation of Illinois has issued a small pamphlet in which are suggested certain rules for writing your congressman if the letters are to have the most effect:

1. Write on a specific issue or principle, and do not try to cover more than one in a letter.
2. Be brief. Tell your point of view and your reasons.
3. Do not follow a form letter. Give your own ideas in your own way. It is the straightforward, sincere letter that commands attention.
4. Be friendly and courteous. Do not be abusive.
5. Do not use carbon copies. Write to each one individually.
6. Write a "thank you" note when one of these men does something you like. They are often criticized, seldom praised.
7. Be sure to sign your letter legibly and give your address.

ARE DOCTORS GOOD BUSINESSMEN?

The 1955 study on "What Americans Think of the Medical Profession" reveals that over 50 per cent of the general physicians polled believe that they themselves are not good businessmen. Fifty-two per cent of the internal medical specialists, 54 per cent of the surgeons and 58 per cent of other specialists agreed.

On the other hand, only 10 per cent of the men in the lay group surveyed said they believe it was "true" that doctors were poor businessmen. Eight per cent said it was "possibly true"; 38 per cent said "false," and 10 per cent said it was "probably false."

A total of 81 per cent of physicians believe they are poor businessmen; 13 per cent disagreed, and 6 per cent had no opinion.

Of the general public questioned, a total of 17 per cent believed doctors are not good bus nessmen; 48 per cent disagreed. The remainir had no opinion.

Reasons the overwhelming majority of phys cians gave for believing they are not good bus nessmen were listed in this order: "They are to busy; they stay out of business because they b come 'easy marks'; they are not trained in bus ness; too many collections, poor records and po management; they are interested only in mec cine; it takes too much experience and obser tion; they don't think about money; they're to softhearted and don't always charge; most of the are not wealthy; they leave small estates and mar debts; they let others handle their business; th are not business-like with patients."

The doctors who believed they *are* good bu nessmen gave these reasons for their opinion "they have investments; they live well and are su cessful; the manner in which most keep colle tions and records is good; they are intelligent ar educated; they make money and generally ha good incomes; they have good personal know edge."

Those laymen who believe doctors are po businessmen gave these reasons for their answer "doctors are too busy, too interested in medici only; they are weak managers and have po records; they are not trained in business; they others handle their business; they are not busine like with patients; they are soft-hearted and doı charge; they don't think much about money."

The 48 per cent of the general public w believe physicians *are* good businessmen say th have this idea because "doctors live well and a successful; they are intelligent, capable and ed cated; they make money and have big incom they are businesslike in their billing and collectir they have investments and many material poss sions; they are busy and have many patients a they charge high fees."

WHAT DO DOCTORS THINK OF SOCIAL SECURITY?

In state surveys made in various parts of t country, the number of doctors who believe i compulsory social security for the profession s less than 10 per cent.

The largest poll tabulated up to February w that taken by the Ohio State Medical Associati. Ballots were sent to 8,360 members. The m question was: "Do you favor extension of O ge and Survivors' Benefits coverage of the Fedal Social Security Program to Physicians?" The llot was accompanied by material prepared by e affirmative and negative sides. There were 912 ballots returned (about 60 per cent). Of ese, twelve could not be tabulated because of egularity of answers. Of the remaining 4,900, arly one-half, 2,441, voted "no," indicating that ey did not want social security under any cirmstance.

Of the 2,459 favoring some form of coverage, 070 said they wanted it on a voluntary basis. nly 370 were in favor of compulsory coverage.

In Indiana, on the basis of 2,333 replies to 513 questionnaires sent out by the Indiana State edical Association, there were 703 doctors who re for some form of social security. Of these, 9 gave their assent to such coverage, provided was voluntary. Only ninety-one wanted a mpulsory program.

The Rhode Island Medical Society and Province Medical Association polled 800 members. sable returns were received from 450. Opposin to any form of social security totaled 152. hose favoring a voluntary system numbered 264. nly thirty-four voted for a compulsory program.

The Arkansas Medical Society sent out about 200 questionnaires and to the end of January ad 836 usable replies. There were 785 votes gainst a compulsory program. Of these, 411 docrs were agreeable to a voluntary coverage, but 74 wanted no part of social security. The proonents of a compulsory plan numbered fifty-one.

The AMA has consistently opposed the inclusn of physicians in any social security program n a compulsory basis. It has stated that it will ot oppose an amendment permitting voluntary articipation.

A poll of Minnesota physicians is now being conucted on the same subject. It is believed that e survey will probably confirm the findings in ther states.

ATASTROPHIC HEALTH INSURANCE OR FEDERAL EMPLOYES

The administration is about ready to present Congress its program for major medical cost surance for the 2,000,000 U. S. civilian emloyes and their 2,500,000 dependents. All U. S. nployes and dependents who are participating the two-year-old federal group life insurance rogram would receive this catastrophic health insurance protection at no cost to themselves. The entire cost—about $32½ million annually—would be paid by the United States.

To varying degrees, hospital, surgical and medical care costs would be covered. The major medical care benefits, however, would not apply until $500 of hospital costs were paid annually by the employe. After that the United States policy would meet 75 per cent of the cost. The employe would be reimbursed for 75 per cent of all surgical costs after he had paid the first $250. He would be expected annually to stand the first $100 and would be reimbursed for 75 per cent of the remainder. The assumption is that in most cases the employe would protect himself against these initial payments by purchase of basic health insurance.

MEDICAL LIBRARY BILL

Senator Hill, (D., Ala), with Senator Kennedy, (D., Mass.), as co-sponsor, has introduced a bill taking the Armed Forces Medical Library from under the Defense Department and setting it up as a separate entity with the name of "National Library of Medicine." They left open the question of whether to place it under the Smithsonian Institution as recommended by the Hoover Commission or under some other agency such as the Department of HEW. One of the points cited by Senator Hill for the bill is that the present library, with its wealth of material, provides considerable information for civilian medical science. Senator Kennedy stressed that the library cannot compete for funds in the Defense Department against the needs and demands of national defense. The bill has been referred to the Senate Labor and Public Welfare Committee, which has no immediate plans for hearings.

The AMA's House of Delegates in June, 1954, urged a new building for the present library and called on the government to give it "immediate priority."

SOME DOCTORS MISS THIS TREAT

The 75 per cent of doctors in general practice who disagreed with the statement, "Compared with their patients, most doctors make too much money" in the poll, "What Americans Think of the Medical Profession," last year apparently agree with the statement that "wealthy doctors, like all wealthy people, miss one of the greatest thrills in life—paying off that last installment!"

The Dean's Page

LEADERSHIP IN MEDICINE

A recent issue of the new *University of Minnesota Medical Bulletin* points out some interesting information concerning alumni of our Medical School. From time to time, the *Bulletin* carries news items concerning our alumni. It has been apparent from these news items that a good many of our alumni occupy positions of importance medically in many parts of this country. It has been particularly impressive, however, to note the manner in which our graduates have become active leaders of medicine in Minnesota.

At the present time, the President, the immediate Past President, both Vice Presidents, the Secretary, the Treasurer, the Speaker of the House of Delegates, and the Chairman of the Council of the Minnesota State Medical Association are alumni of our Medical School. All of the newly installed officers, as well as the out-going president, and the new directors of the Minnesota Academy of General Practice also graduated from Minnesota, as did the new officers of the Southern Minnesota Medical Association and the incoming and retiring presidents of the Northern Minnesota Medical Association. Our alumni have been instrumental in the development and activities of a number of other important medical organizations in this state.

Our entire faculty takes justifiable pride in this record. We believe that it shows that our alumni have not only practiced an excellent brand of medicine but that, in addition, they have assumed their share or more of leadership in the medical community.

HAROLD S. DIEHL, *Dean*
University of Minnesota Medical School

In Memoriam

USTAF A. HEDBERG

Dr. Gustaf A. Hedberg, medical director of Nopeming natorium, Nopeming, Minnesota, died March 27, 1956, Tallahassee, Florida. He was forty-nine years old.

An authority on tuberculosis treatment and control, was awarded the 1955 Dearholt medal for outstand- service in tuberculosis control at the Mississippi lley Conference on tuberculosis last October.

He is credited with originating the first mobile x-ray t for tuberculosis survey in 1943. He is also credited h using new drugs to shorten tuberculosis treatment.

Dr. Hedberg joined the Nopeming staff shortly after received his medical degree from the University of nnesota in 1930.

He was a member of the St. Louis County Medical iety, the Minnesota State Medical Association, the nerican Medical Association, the National Tuberculosis sociation, the American Sanatorium Association, the nnesota Trudeau Society and the Duluth Society of ernal Medicine.

Survivors include his wife, Iris; two daughters, Susan d Karen, both of Nopeming; two sisters, Mrs. Carl ad, Saint Paul Park, and Mrs. John E. Ross, Minne- olis, and a brother, Robert, El Sobrante, California.

ENRY N. KLEIN

Dr. Henry N. Klein, former chief of staff of Saint seph's Hospital, Saint Paul, died April 16, 1956, after long illness.

Dr. Klein practiced medicine for fifty years and served the staffs of Saint John's, Ancker, Miller and Saint ke's Hospitals and the Wilder Dispensary.

He was graduated from the University of Minnesota edical School and held membership in the Ramsey ounty Medical Society, the Minnesota State Medical sociation and the American Medical Association.

A member of the University Club and a veteran of th the Spanish-American War and World War I, . Klein also served as head of the dermatology de- rtment at the Wilder Dispensary.

Survivors include his wife, Josephine E.; a son, Rich- d E., and three grandchildren, all of Saint Paul.

COTT G. LARRABEE

Dr. Scott G. Larrabee, a Saint Paul eye, ear, nose and roat specialist for thirty-three years, died April 2, 1956. was seventy-one years old.

Born in Scarboro, Maine, he was a graduate of Bow- in University in his home state. Dr. Larrabee lived at 80 Iglehart Avenue, Saint Paul.

Survivors include his wife, Nellie; a daughter, Mrs. orge T. Hammond, and three grandchildren, all of int Paul, and two brothers, Alvin, Detroit, Michigan, d Ralph, who still lives in Maine.

HENRY H. LEAVITT

Dr. Henry H. Leavitt, a Minneapolis physician fifty-eight years, died March 18, 1956. He was ninety-four years old.

A native of Waterloo, Iowa, he was the oldest living graduate of Beloit College, Beloit, Wisconsin. He also graduated from Chicago Homeopathic Medical College, came to Minneapolis in 1890 and taught medicine at the University of Minnesota before entering private practice. He retired in 1948. During his retirement, he lived in Phoenix, Arizona, until 1954.

Dr. Leavitt was a general practitioner for many years before specializing in eye, ear, nose and throat medicine.

He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Survivors include three daughters: Mrs. R. M. Bell and Mrs. N. S. Mitchell, Minneapolis, and Mrs. M. N. Clark, Oakland, California. Mrs. Leavitt died in 1954.

JOSEPH A. LEBROWSKE

Dr. Joseph A. Lebrowske, pioneer Minneapolis physician, died April 1, 1956. He was seventy-five years old.

Born in Russia, Dr. Lebrowske received his early education in Minneapolis and graduated from the Minneapolis College of Physicians and Surgeons, formerly affiliated with Hamline University.

The Hennepin County Medical Society, of which Dr. Lebrowske was a member, recently honored him for fifty years of service. He was also a member of the Minnesota State Medical Association, the American Medical Association, the Kenesseth Israel Synagogue and the Woodmen of the World.

Survivors include his wife, Florence; two sons, Bernard, Westport, Connecticut, and Harold, Saint Paul; four daughters, Mrs. David Smith, Los Angeles, California, and Mrs. Martin Yavitz, Mrs. Samuel Held and Mrs. Wilbur Jansen, Minneapolis; and two sisters, Mrs. Ida Hoffman, Minneapolis, and Mrs. Israel Lazarus, Milwaukee, Wisconsin.

FLETCHER W. PENHALL

Dr. Fletcher W. Penhall, a pioneer physician in Morton, Minnesota, died April 2, 1956, at Redwood Falls. He was ninety-three years old.

One of Minnesota's oldest practicing physicians, he retired a year ago after serving the people of Morton for fifty-three years.

Dr. Penhall set up practice in Morton in 1891 after graduating from Bellevue Medical Center in New York. He was born in Brooklin, Ontario, Canada, and took his first medical training at Trinity Medical College, Toronto.

A member of the staff at Willmar State Hospital, Dr. Penhall also served on the Morton Village Council for three years and on the Board of Education for fifteen years. He was a former president of the Camp Release Medical Society, a member of the Renville-Redwood County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Survivors include four daughters: Mrs. John Allen, Mrs. Glenden Judd and Lillith Penhall, Minneapolis, and Mrs. Irving Eustis, Florida. Two other daughters preceded him in death. Lillian, died in 1899, and Jessie, in 1952. Mrs. Penhall died in 1942.

IVAR SIVERTSEN

Dr. Ivar Sivertsen, a Minneapolis physician and surgeon for fifty-one years, died March 17, 1956. He was seventy-nine years old.

Born in Christiansund, Norway, Dr. Sivertsen graduated from Hamline University medical school in 1904. After internship in St. Joseph's Hospital, Saint Paul, he continued his medical studies in Vienna, Austria.

He later taught obstetrics and gynecology at the University of Minnesota.

Dr. Sivertsen retired from medical practice last July. He was one of the original staff members of Fairview Hospital. Earlier this year, he retired from the State Board of Medical Examiners, to which he had been appointed in 1931.

He was also a founder of Central Lutheran church, a charter member of the Minneapolis Club and a Shriner. He served as an army captain during World War I.

A member of the founders' group of the American Board of Surgery, Dr. Sivertsen was also a fellow of the American College of Surgeons, a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Survivors include his wife, Maybelle; two sons, Ivar, Jr., San Jose, California., and John W., Akron, Ohio; three daughters, Wilma Clare, New York, and Anne and Mrs. Margaret Larson, both of Minneapolis, and two brothers, Dr. Andrew and John A., both of Minneapolis.

JOHN E. SOPER

Dr. John E. Soper, Minneapolis, died March 24, 1956. He was eighty-nine years old.

Dr. Soper, a University of Minnesota graduate, was captain of the 151st Field Artillery medical corps in World War I. He was chairman of the National Cemetery Association; chairman of Soldiers Home Committee; national vice president of Rainbow Division Association; Spanish War Veterans, and Sons of Union Veterans. He was also active in American Legion, DAV and VFW activities and was a past exalted ruler of Elk Lodge 44 and a member of Lynnhurst Masonic Lodge.

He practiced medicine in Norwood and Delano, Minnesota, for twenty-one years and served as mayor of Norwood and as Carver County coroner.

Surviving is his wife, Mildred E. Soper.

GREGORY VAN BEECK

Dr. Gregory Van Beeck, a native of Hastings, M. nesota, died March 13, 1956, in Big Springs, Texas. e was sixty-five years old.

Dr. Van Beeck graduated from the University of M. nesota medical school and practiced for two year t Mazeppa, Minnesota. He later entered the United St s Public Health Service and was assigned to posts all the United States, Europe and Central America.

Eight months ago, he resigned his position as mec l director of the Public Health Service.

Funeral services were held in Hastings, March 19

Survivors include his wife, Margaret; a brother, C ens, and a cousin, Mrs. Nick Conzemius, both of H ings.

HENRY JOURNEAY WELLES

Dr. H. Journeay Welles, former deputy corone of Hennepin County, died February 26, 1956, in Mi apolis. He was eighty years old.

Dr. Welles was deputy coroner from 1943 to 195

A 1901 graduate of the University of Minn a medical school, he practiced medicine in Minnea is fifty-five years. He was a member of the Henn n County Medical Society and the Minnesota State M i-cal Association.

Dr. Welles was a past president of Zuhrah Sh e patrol and a member of Alpha Delta Phi and Phi a Pi fraternities.

Survivors include his wife, Bess, and a daughter, B y

WILLIAM E. WRAY

Dr. William E. Wray, physician at Campbell, Mi e-sota, for forty-four years, died February 26, 1956 in Breckenridge. He was seventy-seven years old.

He was a graduate of the University of Illinois me al school, class of 1897. After graduation, Dr. Wray se d one year in the medical corps of the U. S. Army du g the Spanish-American War. During World War I e served as a major in the 155th Coast Artillery.

A member of the staff of St. Francis Hospital, B k-enridge, and the Lake Region Hospital, Fergus Fall ne also served as civil defense chairman for his comm ty and as a member of the Red Cross board. He w a member of the Campbell school board for many y rs, a member of the Masonic Lodge of Campbell, the V.W. and the American Legion.

Dr. Wray belonged to the Park Region District nd County Medical Society, the Minnesota State Me cal Association and the American Medical Association.

In 1947, staff members of St. Francis Hospital, B k-enridge, and their wives honored Dr. Wray at a bar e on the occasion of his completion of fifty years of dical service.

Survivors include his daughter, Dorothy; his s er Mrs. R. S. Cheney, Kerrville, Texas; and his bro er, Edward, Evanston, Illinois. A son, William Edgar, re ceded him in death in 1922 and Mrs. Wray died an-uary 15, 1956.

Meetings and Announcements

EDICAL MEETINGS

ate

MINNESOTA STATE MEDICAL ASSOCIATION, nual meeting, Mayo Civic Auditorium, Rochester, ay 21-23, 1956.

Minnesota Society of Obstetrics and Gynecology, fall eting, Rochester, Minnesota, September 22. Dr. Ed- rd A. Banner, secretary, Rochester, Minnesota.

Northwest Pediatric Society, spring meeting, Roches- r, May 22, in conjunction with meeting of Minnesota ate Medical Association. Secretary, Dr. T. C. Paper- ıster, Minneapolis.

ational

American Association of Blood Banks, ninth annual eting, Somerset Hotel, Boston, Massachusetts, Sep- mber 3-5. Secretary Marjorie Saunders, 725 Doc- rs Building, 3707 Gaston Ave., Dallas, Texas.

American Cancer Society and National Cancer Insti- te, Third National Cancer Conference, Sheraton-Cad- ac Hotel, Detroit, Michigan, June 4-6. Write National ancer Conferences Coordinator, American Cancer So- ety, 521 West 57th Street, New York 19, New York.

American Ophthalmological Society, Hot Springs, Vir- nia, May 31 to June 2.

Medical Library Association, fifty-fifth annual meeting, otel Statler, Los Angeles, California, June 18-22. Write rs. Ella Crandall, Libraian, Los Angeles, County Gen- al Hospital, 1200 North State Street, Los Angeles 33, alifornia.

Microbiological Institute, ninth annual meeting, De- artment of Biological Sciences, Purdue University, afayette, Indiana, June 4-9. Write Division of Adult ducation, Engineering Administration Building, Purdue niversity, Lafayette, Indiana.

Minnesota-Dakota-Manitoba Orthopedic Society, an- ıal meeting, Red Wing, Minnesota, September 7 and 8. r. Hollis Ahlrin, secretary, Rapid City, South Dakota.

Symposium for General Practitioners on Tuberculosis ıd Other Chronic Pulmonary Diseases, fifth annual ieeting, Saranac Lake, New York, July 7-13. Dr. Ed- ard N. Packard, general chairman, Symposium for eneral Practitioners, P.O. Box 262, Saranac Lake, ew York.

Third National Cancer Conference, Detroit, Michigan, ıne 4-6.

West Virginia State Medical Association, 89th annual ieeting, The Greenbrier, White Sulphur Springs, West irginia, August 23-25.

International

Canadian Medical Association, Quebec, P.Q., Canada, June 10-14. Dr. Arthur D. Kelly, secretary, 150 St. George St., Toronto 5., Ontario, Canada.

Congress of International Society of Hematology, Hotel Somerset, Boston, Massachusetts, August 27-September 1. Dr. W. C. Moloney, secretary, 39 Bay State Road, Boston, Massachusetts.

European Congress of Cardiology, Stockholm, Sweden, September 10-14. Dr. Karl E. Grewin, secretary, Sodersjukhuset, Stockholm, Sweden.

Inter-American Congress of Cardiology, Havana, Cuba, November 4-10. Dr. Ramon Aixala, Apartado 2108, Havana, Cuba.

International College of Surgeons, European meetings: Paris, May 10; Nantes, May 14; Berne, May 17; Rome, May 23; Vienna, May 30.

International Congress of Clinical Chemistry, Hotel New Yorker, New York, September 9-14. Secretary, John G. Reinhold, 711 Maloney Building, University of Pennsylvania, Philadelphia 4, Pennsylvania.

International Congress of Gastroenterology, London, England, July 18-21. Herman Taylor, secretary, London Hospital, White Chapel, London E. 1, England.

International Congress of Internal Medicine, Madrid, Spain, September 19-23. Dr. J. C. DeOya, secretary, No. 90, Madrid, Spain.

International Congress of International College of Surgeons, Palmer House, Chicago, Illinois, September 9-13. Dr. Max Thorek, secretary general, 1516 Lake Shore Drive, Chicago, Illinois.

International Congress of Radiology, Mexico, D. F., Mexico, July 22-28. Dr. Jose Noriega, secretary, Tepic 126 (2 e piso), Mexico, D. F. 7, Mexico.

International Congress of World Confederation for Physical Therapy, Statler Hotel, New York, New York, June 17-23 Mildred Elson, American Physical Therapy Association, 1790 Broadway, New York 19, New York.

International Congress on Diseases of the Chest, Cologne, Germany, August 19-23. Murray Kornfeld, executive director, 112 East Chestnut St., Chicago 11, Illinois.

Pan American Congress on Cancer Cytology, Miami, Florida, January 8-12, 1957. Dr. J. Ernest Ayre, chairman, 1155 N. W. 14th St., Miami, Florida.

World Medical Association, Havana, Cuba, October 9-15. Dr. Louis H. Bauer, secretary general, 345 East 46th St., New York 17, New York.

AMERICAN CANCER SOCIETY FELLOWSHIPS

The American Cancer Society has announced that its program of clinical fellowships, which began in 1948, will continue through the institutional years, July 1, 1957 to June 30, 1958, with fellowships commencing July 1, 1957. Applications for fellowships should be sent to Dr. Brewster S. Miller, American Cancer Society, 521 West 57th Street, New York 19, New York, via the executive officer of the teaching institution.

AMERICAN COLLEGE OF GASTROENTEROLOGY ANNOUNCES WRITING CONTEST

The American College of Gastroenterology, in cooperation with the Ames Company of Elkhart, Indiana, announces the 1956 Ames Award contest for the best papers in gastroenterology.

For fellows in gastroenterology, residents and internes the first prize will be $500, with a second prize of $250. In addition a prize of $250 will be given for the best paper published in the *American Journal of Gastroenterology* during the year ending June 30. Papers must be submitted before July 15.

For further information, write the American College of Gastroenterology, 33 West 60th Street, New York 23, New York.

MINNESOTA ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY

New officers of the Minnesota Academy of Ophthalmology and Otolaryngology for 1956-1957 are Dr. Karl E. Sandt. Minneapolis, president; Dr. John Peterson, Duluth. first vice president; Dr. John Erick, Rochester, second vice president; Dr. Malcolm McCannel. Minneapolis, secretary-treasurer.

Chairman of the council is Dr. George Tangen, Minneapolis, and members of the council include Dr. John Wendland, Dr. Walter Fink, Dr. Sandt and Dr. McCannel, all of Minneapolis; Dr. Frank Adair, St. Paul, and Dr. Hobart Johnson, Mankato.

The organization meets on the second Friday of the month from November to May, alternating between the Minneapolis Club in Minneapolis and the Minnesota Club in St. Paul.

CAMP COURAGE OPENS IN JUNE

Camp Courage. Minnesota's only camp especially designed for physically handicapped children and adults, opens its second season June 17.

The camp is maintained by the Minnesota Society for Crippled Children and Adults (the Easter Seal Society). Located on Cedar Lake, about four miles northwest of Minneapolis, it offers regular activities as well as speech and physical therapy on recommendation from a physician. A trained occupational therapist administers the arts and crafts program.

The camp is open to all types of physically handicapped children and adults, including those who are blind, deaf or have speech problems. Minimum age is eight. At present, the camp is not accepting children who are mentally retarded or emotionally disturbed. Epileptics, diabetics and enuretics are screened and evaluated on individual merit by an admissions committee upon medical recommendation. No one is ever refused admission because of race, creed, color or inability to pay.

Physicians knowing prospective campers should contact their local Easter Seal chairman or Toy Jambeck, Camp Director, Easter Seal Society, 1639 Hennepin Ave., Minneapolis 3, Minnesota.

Woman's Auxiliary

BABY SITTER PROJECT FOR ST. LOUIS COUNTY AUXILIARY

Mrs. L. J. Leonard

A Duluth project which stimulated considerable int-
est was presented by Mrs. H. E. Bakkila during the M
Winter Board meeting in Saint Paul.

The Home Safety Committee of the Duluth Woma
Institute formed a Baby Sitters' Council in 1950 to m
the need to educate baby sitters in safety matters. T
St. Louis County Medical Auxiliary was approached w
the problem and agreed to participate in the program.

The Auxiliary supplied printed cards, about 8 x
inches, in the form of a bulletin which could be tack
on the wall of the home in a conspicuous spot. T
card gave these six emergency facts in bold type—w
proper telephone numbers and other instructions:

1. Parents' name and address where they could
   reached; also where else to get help in emergenc
2. Serious injury to the baby.
3. Fire.
4. Sudden sickness.
5. Choking.
6. Gas, water or light failure.

These cards were given to all attending the ann
Baby Sitters' workshops which have been held since 19

From a group of 180 at the first workshop, the numl
has increased to the point where the last two meeti
have been held at the Shrine auditorium. Attending v
a capacity-size group of baby sitters and interested adu

Stunts, movies, door prizes and group singing ha
been added to the programs to stimulate interest.

By constant repetition of safety rules, the sponsors ho
to train more competent and more responsible ba
sitters.

Inquiries on the operation of this plan have been
ceived from all over the United States.

Members of the St. Louis County Auxiliary are to
commended for their participation in this program a
for their contribution to its success.

NATIONAL CONVENTION

Mrs. G. E. Harmon, State Auxiliary Publicity Ch
man, has received a letter from Margaret Wolf, natio
Executive Secretary, extending a cordial invitation
Auxiliary members to participate in all social funct
and Auxiliary sessions of the national convention, J
11-15, in Chicago. Headquarters will be at the Conr
Hilton Hotel. Tickets for all functions will be availa
only at the registration desk. There will be a hospita
room in the Normandy Lounge.

Mrs. Harmon has studied the program and states t
it looks very interesting and most worthwhile.

General Interest

Minnesota physicians are invited to submit items of "general interest" concerning themselves or their colleagues to MINNESOTA MEDICINE, 2642 University Avenue, St. Paul 14, Minnesota. Only the facts are needed—who? what? where? when? why?—since items are rewritten for uniformity of style.

* * *

Dr. Gordon R. Kamman and attorney **Charles Murnane**, St. Paul, discussed "Medical-Legal Relationships" at a joint meeting of the Southwestern Minnesota Medical Society and Bar Association in Worthington on April 9.
